Abstract: Over the last decades, the energy market around the world has reshaped due to accommodating the high penetration of renewable energy resources. Although renewable energy sources have brought various benefits, including low operation cost of wind and solar PV power plants, and reducing the environmental risks associated with the conventional power resources, they have imposed a wide range of difficulties in power system planning and operation. Naturally, classical optimal power flow (OPF) is a nonlinear problem. Integrating renewable energy resources with conventional thermal power generators escalates the difficulty of the OPF problem due to the uncertain and intermittent nature of these resources. To address the complexity associated with the process of the integration of renewable energy resources into the classical electric power systems, two probability distribution functions (Weibull and lognormal) are used to forecast the voltaic power output of wind and solar photovoltaic, respectively. Optimal power flow, including renewable energy, is formulated as a single-objective and multi-objective problem in which many objective functions are considered, such as minimizing the fuel cost, emission, real power loss, and voltage deviation. Real power generation, bus voltage, load tap changers ratios, and shunt compensators values are optimized under various power systems' constraints. This paper aims to solve the OPF problem and examines the effect of renewable energy resources on the above-mentioned objective functions. A combined model of wind integrated IEEE 30-bus system, solar PV integrated IEEE 30-bus system, and hybrid wind and solar PV integrated IEEE 30-bus system are performed using the equilibrium optimizer technique (EO) and other five heuristic search methods. A comparison of simulation and statistical results of EO with other optimization techniques showed that EO is more effective and superior.

Keywords: Active power loss; total generation cost; emission index; optimal power flow; equilibrium optimizer; solar PV integrated IEEE 30-bus system; wind integrated IEEE 30-bus system; hybrid wind and solar PV integrated IEEE 30-bus system

1. Introduction

1.1. Background

The urgent need for reducing the fuel cost of the conventional power generation units and minimizing the greenhouse gases emitted from the thermal power generators have led various electric power companies to go toward utilizing renewable energy resources. Furthermore, advanced technologies of renewable energy resources have contributed significantly to be the most inexpensive and environmentally friendly. Integrating wind and solar PV in proper locations and appropriate settings of the variables of the conventional power networks may have a significant impact on the performance of power system control and operation.

31 To make the modeling of wind and solar PV more accurate and realistic, the Weibull probability distribution
32 function was used to forecast the wind speed [1]-[2]. Whereas lognormal probability distribution function is used
33 to mimic the intermittent nature of solar irradiance in [3] [4].

34 1.2. Literature review

35 Numerous publications in the literature studied the optimal power flow (OPF) problem for systems
36 consisting of conventional power generation and renewable-energy power plants. Deterministic, stochastic
37 or hybrid optimization methods are used extensively to address the issues associated with increased penetration
38 of non-dispatchable renewable energy, advanced controls such as FACTS devices and deregulated electricity
39 markets.

40 Various conventional optimization techniques are used to solve the OPF problem. For instance, continuous
41 nonlinear programming was proposed [5]. An extended conic quadratic format [6] is presented to solve the
42 economic dispatch and decrease real power loss. Besides, the predictor-corrector interior point algorithm is
43 proposed to fit the OPF for solving nonlinear programming problems [7]. Quadratic programming is used to derive
44 a loss formula based on the incremental power flow [8]. Sequential quadratic programming is used to address large
45 scale OPF; it also depends on transforming the original problem to a sequence of linearly constrained sub-problem
46 by applying an augmented lagrangian [9]. Mixed-integer linear programming to minimize transmission losses and
47 reactive generator outputs are adapted [10]. Although these methods have excellent convergence characteristics,
48 they have various drawbacks, including failing to find the global solution because of non-convexity and facing
49 difficulty while handling the problems with non-differentiable and discontinuous objective functions.

50 Recently, metaheuristic optimization algorithms have been gaining much attention due to flexibility, free of
51 derivation, and local optima avoidance. Thus, single and multi-objective optimization methods overcome the
52 shortcomings attributed to classical techniques. A gravitational search algorithm to find the optimal solution for
53 OPF and IEEE 30-bus and 57-bus systems are examined [11]. The basic fuel cost, voltage profile, voltage stability,
54 and non-smooth quadratic cost are minimized and optimized using a differential evolution algorithm [12]. The
55 Black hole-based optimization method is used to address the OPF problem for IEEE 30-bus and Algerian 59-bus
56 power systems [13]. Constrained OPF problem for IEEE 30-bus, 57-bus, and 118-bus is optimized using a moth
57 swarm algorithm [14]. A multi-objective OPF to minimize the generation cost and environmental pollution using
58 a fuzzy membership function to choose a compromise solution from the Pareto optimal solutions is discussed
59 [15]. The fuel cost, voltage deviation, and real power loss are minimized as a multi-objective OPF problem
60 using a gravitational search algorithm [16]. A modified teaching learning-based optimization algorithm added a
61 self-adapting wavelet mutation strategy and a fuzzy clustering [17]. A hybrid of fuzzy evolutionary and swarm
62 optimization is proposed to minimize the cost of active power generation and real power losses [18].

63 A fuzzy-based modified bee colony is presented to solve discrete OPF using multi-objective mixed integer
64 nonlinear [19]. Emission, real power losses, and voltage deviation are all minimized as a multi-objective
65 OPF using a multi-objective modified imperialist competitive algorithm [20]. The particle swarm optimization
66 and the shuffled frog leaping algorithm are hybridized to solve OPF using the generator's constraints such as
67 prohibited zones and valve point effect [21]. A chaotic invasive weed optimization algorithm is proposed to
68 solve the OPF problem with non-smooth and non-convex fuel cost curves [22]. Brainstorming optimization
69 and teaching-learning optimization are hybridized to minimize the fuel cost of thermal generation units [23]. A
70 hybrid optimization algorithm is based on sequential quadratic programming to generate an initial population.
71 Then a differential evolution took that population to find the optimal solution more effectively and it was used to
72 minimize the fuel cost with valve point and the transmission line real losses [24].

73 A growing and considerable effort have been made in recent years to solve and model the OPF problem,
74 including renewable energy sources. The OPF problem with taking into account uncertainties in the wind, solar,
75 and load forecast and optimized using a genetic algorithm and two-point estimate method [25]. A hybrid method
76 called moth swarm algorithm and gravitational search algorithm is used to solve the problem of OPF, including
77 wind power [26]. A modified two-point estimation method is used to solve probabilistic OPF incorporating
78 wind and solar photovoltaic [27]. Hybrid wind photovoltaic power systems are optimized using the unscented
79 transformation method, which can carry out probabilistic OPF with high accuracy and less computational time

[28]. The OPF, including wind is optimized using a fuzzy-based particle swarm optimization. A fuzzy set modeled the forecast load demand and wind speed [29].

Besides, OPF incorporating wind power energy is optimized by a hybrid algorithm called a hybrid dragonfly with aging particle swarm optimization [30]. Adaptive differential evolution with proper constraint handling method is addressed OPF, including wind and solar. The forecast wind and solar photovoltaic are modeled using Weibull and lognormal probability distribution functions [31]. An optimal reactive power dispatch with solar photovoltaic power and its impact on minimizing real power losses is addressed using the Jaya algorithm to solve this issue [32]. A constrained multi-objective population external optimization method in [33] is presented to minimize the fuel cost and emission in the presence of renewable energy sources. A grey wolf optimization algorithm in [34] was proposed to tune the parameters of a thyristor controlled series compensator and address OPF, including wind and solar power. A gbest guided artificial bee colony optimization in [1] was to find the optimal setting of conventional and renewable power generation.

1.3. Contribution and paper organization

In the present work, an equilibrium optimizer [35], which is a novel optimization method inspired by controlling the volume mass balance model for estimating both equilibrium and dynamic states, is used to prove its performance in solving the OPF problem. It is implemented on i) IEEE 30-bus system, ii) wind integrated IEEE 30-bus system, iii) solar PV integrated IEEE 30-bus system, and iv) hybrid wind and solar PV integrated IEEE 30-bus system. Real power loss minimizations, total cost minimization of generating units and emission index minimization are considered to be the objective functions of the OPF problem. Weibull and lognormal probability distribution functions are used to model the wind speed and solar irradiance to forecast the output power of wind and solar PV systems. Furthermore, aiming to fill the gap in the literature, this paper investigates the impact of the presence of only wind or only solar PV or both of them on enhancing the objective functions of the OPF problem. In addition, a comprehensive statistical analysis for the equilibrium optimizer technique (EO) and other optimization techniques are analysed.

The rest of this paper is organized as follows: the formulation of OPF problem is described in Section 2. Then, a mathematical models of wind and solar PV plants are introduced in Section 3. Section 4 presents the equilibrium optimizer technique (EO) and its implementation to solve the OPF problem. Simulation results are explained in Section 6. Finally, Section 7 draws the conclusion of this work.

2. Problem formulation of OPF

2.1. General structure of OPF

Generally, OPF aims to minimize some objective functions. f_o is the objective function to be minimized, and h and g are the equality and inequality constraints in the power system network, OPF can be expressed as [14,36]:

$$\begin{aligned} & \text{Minimize} && f_o(x, u) \\ & \text{Subject to} && g(x, u) \leq 0 \\ & && h(x, u) = 0 \end{aligned} \quad (1)$$

x is a state vector of dependent variables including real power of swing generator (P_{G_i}), (V_{L_i}) is the voltage magnitude of load buses, (Q_{G_i}) is the reactive power of generator at i_{th} bus and (S_{l_i}) is the loading of the i_{th} transmission line. x can be expressed as follows [14,36]:

$$x = [P_{G_1}, V_{L_1}, \dots, V_{L_{npq}}, Q_{G_1}, \dots, Q_{G_{N_G}}, S_{l_1}, \dots, S_{l_{n_l}}]^T \quad (2)$$

where npq , and n_l are the number of PQ buses and transmission lines. S_l and n_l are loading of transmission lines and the number of transmission lines, respectively.

u is a vector consisting of control variables, (P_{G_i}) is the real power of all generators excluding swing generator, (V_{G_i}) is the voltage magnitude of generators, (TS) is the branch transformer tap, and (Q_C) is the shunt capacitors. u can be expressed as follows [14,36]:

$$u = [P_{G_2}, \dots, P_{G_{NG}}, V_{G_1}, \dots, V_{G_{NG}}, Q_{C1}, \dots, Q_{C_{N_c}}, TS_1, \dots, TS_{N_T}]^T \quad (3)$$

112 where, NG , N_c and N_T are the number of generators, shunt VAR compensator and transformers, respectively.

113 2.2. Objective functions of OPF

114 Here, the first four cases dealt with solving single objective OPF and the last one addressed the
115 multi-objective OPF.

- Case 1: real power loss minimization

Due to the presence of the inherent resistance for the transmission lines, the aim of this function is to minimize the active power losses and it is expressed as [14,36]:

$$f_o(x, u) = P_{loss} = \sum_{q=1}^{nl} G_{q(ij)} (V_i^2 + V_j^2 - 2V_i V_j \cos(\delta_{ij})) \quad (4)$$

116 Where $G_{q(ij)}$ is the conductance of q_{th} transmission line, and V_i and V_j are the voltage magnitude of
117 terminal buses of transmission line.

- Case 2: emission index minimization

In the present case, the target is to reduce the harmful gases emission from the thermal generation units, and the coefficients of the gas emission of the thermal power generators are given in Table 1. Emission in tons per hour (t/h) can be described by [14,36]:

$$f_o(x, u) = E = \sum_{i=1}^{NG} [(\alpha_i + \beta_i P_{G_i} + \gamma_i P_{G_i}^2) * 0.01 + \omega_i e^{\mu_i P_{G_i}}] \quad (5)$$

118 where α , β , γ , ω and μ are the emission coefficient and they are given in Table 1.

Table 1. Emission coefficients of thermal power generating units.

| Generator | Bus | α | β | γ | ω | μ |
|-----------|-----|----------|---------|----------|----------|-------|
| G1 | 1 | 4.091 | -5.554 | 6.49 | 0.0002 | 2.857 |
| G2 | 2 | 2.543 | -6.047 | 5.638 | 0.0005 | 3.333 |
| G3 | 5 | 4.258 | -5.094 | 4.586 | 0.000001 | 8 |
| G4 | 8 | 5.326 | -3.55 | 3.38 | 0.002 | 2 |
| G5 | 11 | 4.258 | -5.094 | 4.586 | 0.000001 | 8 |
| G6 | 13 | 6.131 | -5.555 | 5.151 | 0.00001 | 6.667 |

- Case 3: Basic fuel cost minimization

The relationship between fuel cost (\$/h) and the power generated from the thermal generating units can be approximately given by the quadratic relationship and it is expressed as [14,36]:

$$f_o(x, u) = FC = \sum_{i=1}^{NG} a_i + b_i P_{G_i} + c_i P_{G_i}^2 \quad (6)$$

119 where a_i , b_i , c_i are the cost coefficient of the thermal generators and these coefficients are provided in
120 Table 2.

Table 2. Cost coefficients of the thermal power generators.

| Generator | Bus | a | b | c |
|-----------|-----|---|------|---------|
| G1 | 1 | 0 | 2 | 0.00375 |
| G2 | 2 | 0 | 1.75 | 0.0175 |
| G3 | 5 | 0 | 1 | 0.0625 |
| G4 | 8 | 0 | 3.25 | 0.00834 |
| G5 | 11 | 0 | 3 | 0.025 |
| G6 | 13 | 0 | 3 | 0.025 |

- Case 4: Voltage deviation minimization

The voltage deviation index is the cumulative deviation of all load buses from nominal value of unity. It also play a significant role in keeping the voltage quality and security of the electrical power network. This case is expressed as [14,36]:

$$f_o(x, u) = VD = \left(\sum_{p=1}^{NL} |V_{L_p} - 1| \right) \quad (7)$$

- Case 5: Minimization of basic the fuel cost, emission index, voltage deviation and the real power losses. The aim of this case is to reduce quadratic fuel cost, active power transmission losses, environmental emission index and voltage deviation index simultaneously. It can be defined as follows [14,36]:

$$f_o(x, u) = \sum_{i=1}^{NG} a_i + b_i P_{G_i} + c_i P_{G_i}^2 + \lambda_p \times P_{loss} + \lambda_{VD} \times VD + \lambda_E \times E \quad (8)$$

121 where λ_p , λ_{VD} and λ_E are weight factors and they are assumed to be 22, 21 and 19, respectively as in [14].

122 2.3. Constraints

123 The constraints of OPF are usually categorized into [14,36]:

1. Equality constraints

The equality constraints of OPF are usually represented by the load flow equations:

$$P_{G_i} - P_{D_i} = V_i \sum_{k=1}^{N_B} V_k (G_{ik} \cos \theta_{ik} + B_{ik} \sin \theta_{ik}) \quad (9)$$

$$Q_{G_i} - Q_{D_i} = V_i \sum_{k=1}^{N_B} V_k (G_{ik} \sin \theta_{ik} - B_{ik} \cos \theta_{ik}) \quad (10)$$

124 where P_{D_i} , Q_{D_i} , N_B , and θ_{ik} are the active and reactive load demand, the reactive load demand, the number
125 of buses and the angle difference between bus i and k , respectively. G_{ik} and B_{ik} are the transfer and
126 susceptance conductance.

127 2. Inequality constraints

128 It can be defined by operating limits on the equipment of the power system, transmission loading and
129 voltage of load buses.

(a) Constraints of thermal and renewable energy generating units

$$V_{G_{i,min}} \leq V_{G_i} \leq V_{G_{i,max}} \quad i = 1, \dots, N \quad (11)$$

$$P_{G_{i,min}} \leq P_{G_i} \leq P_{G_{i,max}} \quad i = 1, \dots, N \quad (12)$$

$$Q_{G_{i,min}} \leq Q_{G_i} \leq Q_{G_{i,max}} \quad i = 1, \dots, N \quad (13)$$

(b) Constraints of the transformer tap setting

$$TS_{k,min} \leq TS_k \leq TS_{k,max} \quad k = 1, \dots, N_T \quad (14)$$

(c) constraints of the shunt compensator

$$Q_{C,j,min} \leq Q_C \leq Q_{C,j,max} \quad j = 1, \dots, N_C \quad (15)$$

(d) Constraints of the voltages at load buses

$$V_{Lr,min} \leq V_{Lr} \leq V_{Lr,max} \quad r = 1, \dots, N_L \quad (16)$$

(e) Constraints of the transmission line loading

$$S_{lv} \leq S_{lv,max} \quad v = 1, \dots, n_l \quad (17)$$

130 2.4. Constraint handling

In order to decline the infeasible solutions of OPF and keep the dependent variables within the allowable ranges, a penalty function was modeled and added to the objective functions defined in Section 2.2 [14,36].

$$penalty = K_p (P_{G1} - P_{G1}^{Lim})^2 + K_Q \sum_{i=1}^{NG} (Q_{Gi} - Q_{Gi}^{Lim})^2 + K_V \sum_{i=1}^{NL} (V_{Li} - V_{Li}^{Lim})^2 + K_S \sum_{i=1}^{nl} (S_{li} - S_{li}^{Lim})^2 \quad (18)$$

131 where K_Q , K_p , K_V and K_S are the values of penalty factors associated with generation reactive power, generation
132 real power of the swing generator, load bus voltages and line flow of transmission lines. They are assumed
133 to be 100, 100, 100, and 100,000, respectively [14,37], and x^{Lim} is the value of the violated limit of dependent
134 variables(x). It is equal to x^{max} in case of $x > x^{max}$ or x^{min} in case of $x < x^{min}$.

135 3. Mathematical models of the wind & solar power generating units

136 3.1. Wind power units

137 3.1.1. Uncertain and power model of wind turbines

The wind speed of the wind turbines follows the Weibull probability distribution function. The characteristic of the output power generated by the wind turbine is a random variable depending on wind speed. The Weibull probability distribution function with dimensionless shape factor (k) and scale factor (c) is used to model the wind speed $f_{(v)}(v)$. The wind speed ($f_{(v)}(v)$) can be expressed mathematically as [1,2,38,39]:

$$f_v(v) = \frac{k}{c} \left(\frac{v}{c}\right)^{k-1} \times e^{-\left(\frac{v}{c}\right)^k} \quad (19)$$

Mean of Weibull distribution (M_{wbl}) can be expressed as [31,40–42]:

$$M_{wbl} = c * \Gamma(1 + K^{-1}) \quad (20)$$

The electrical energy generated by a wind turbine ($P_w(v)$) is the result of converting of the kinetic energy of wind and it can be estimated as [1,2,38,39]:

$$P_w(v) = \begin{cases} 0 & v < v_{in} \text{ and } v > v_{out} \\ P_{wr} \left(\frac{v - v_{in}}{v_r - v_{in}} \right) & v_{in} \leq v \leq v_r \\ P_{wr} & v_r < v \leq v_{out} \end{cases} \quad (21)$$

138 where (P_{wr}), (v_{in}), (v_{out}) and (v_r) are the rated power of the wind turbine, the cut-in wind speed of the wind
139 turbine, the cut-out wind speed and the rated wind speed, respectively.

140 3.1.2. Calculation of direct, underestimation and overestimation cost of wind power

The direct cost of wind power plant can be defined as[31,40–42]:

$$C_{w,j}(P_{ws,j}) = g_j P_{ws,j} \quad (22)$$

where g_j is the direct cost coefficient of wind plant. The cost function is overestimated because the actual generated power from the wind turbine is less than the estimated power by mathematical equations. The overestimation cost is used for reverse the requirements when the estimated output power of the wind turbine is more than actual output power. Reserve cost for the j^{th} wind turbine can be defined as [31,40–42]:

$$\begin{aligned} C_{Rw,j}(P_{ws,j} - P_{wav,j}) &= K_{Rw,j}(P_{ws,j} - P_{wav,j}) \\ &= K_{Rw,j} \int_0^{P_{ws,j}} (P_{ws,j} - P_{w,j}) f_w(P_{w,j}) dP_{w,j} \end{aligned} \quad (23)$$

where $K_{Rw,j}$, $P_{wav,j}$, $P_{ws,j}$ and $f_w(P_{w,j})$ are the reserve cost coefficient pertaining to j^{th} wind turbine, the actual available power from the same plant, the estimated power from the j^{th} wind turbine and the wind power probability density function for j^{th} wind turbine. Underestimation cost function of the wind turbine is due to not using the whole power which is generated from the wind turbine. In other words, when the generated power from the wind turbine is more than the estimated power, underestimation cost function is applied as a penalty due to waste the surplus power. The Penalty cost for the j^{th} wind turbine can be defined as [31,40–42]:

$$\begin{aligned} C_{Pw,j}(P_{wav,j} - P_{ws,j}) &= K_{Pw,j}(P_{wav,j} - P_{ws,j}) \\ &= K_{Pw,d} \int_{P_{ws,j}}^{P_{wr,j}} (P_{w,j} - P_{ws,j}) f_w(P_{w,j}) dP_{w,j} \end{aligned} \quad (24)$$

where $K_{Pw,j}$ is a coefficient represent the penalty cost for the j^{th} wind turbine and $P_{wr,j}$ is the rated output power which is generated from the j^{th} wind turbine. As shown in Section 3.1.2, the total cost of wind power turbines (C_T^W) can be described as follows:

$$C_T^W = \sum_{j=1}^{N_w} C_{w,j}(P_{ws,j}) + C_{Rw,j}(P_{ws,j} - P_{wav,j}) + C_{Pw,j}(P_{wav,j} - P_{ws,j}) \quad (25)$$

141 where N_w is the number of wind power turbines.

142 3.2. Solar power units

143 3.2.1. Uncertain and power model of solar PV plants

Solar irradiance can be modelled by Lognormal probability distribution function due to its uncertain and stochastic nature. The Lognormal probability distribution is a function of solar irradiance (G) with mean μ and standard deviation σ , it can be expressed mathematically as [3],and [4]:

$$f_G(G) = \frac{1}{G\sigma\sqrt{2\pi}} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right) G > 0 \quad (26)$$

Mean of lognormal distribution M_{lgn} can be expressed as:

$$M_{lgn} = \exp\left(\mu + \frac{\sigma^2}{2}\right) \quad (27)$$

The main role of PV systems is to convert the solar irradiance to electrical energy. The output power of PV system ($P_s(G)$) as a function of irradiance can be estimated as [31,40]:

$$P_s(G) = \begin{cases} P_{sr} \frac{G^2}{G_{std} R_c} & \text{for } 0 < G < R_c \\ P_{sr} \frac{G}{G_{std}} & \text{for } G \geq R_c \end{cases} \quad (28)$$

144 where G_{std} represents the solar irradiance in standard environment, R_c is a certain irradiance point, and P_{sr} is the
145 rated output power which is generated from the solar PV system.

146 3.2.2. Calculation of direct, underestimation, and overestimation cost of solar PV power

The direct cost of solar power plant can be defined as [31,40] :

$$C_{s,k}(P_{ss,k}) = h_k P_{ss,k} \quad (29)$$

where h_k is a coefficient represents the direct cost of solar photovoltaic plant.

The same case as in wind energy system, solar energy system involves overestimation and underestimation cost due its uncertain output power. Reserve cost for the overestimation of k^{th} solar PV system is [31,40]:

$$\begin{aligned} C_{R_s,k}(P_{ss,k} - P_{sav,k}) &= K_{R_s,k}(P_{ss,k} - P_{sav,k}) \\ &= K_{R_s,k} * f_s(P_{sav,k} < P_{ss,k}) * \\ &\quad [P_{ss,k} - E(P_{sav,k} < P_{ss,k})] \end{aligned} \quad (30)$$

where $K_{R_s,k}$ is a coefficient represents the reserve cost pertaining to k^{th} solar PV system, $P_{sav,k}$ is the actual available power from the same plant, $f_s(P_{sav,k} < P_{ss,k})$ is the probability of solar power shortage occurrence than the scheduled power ($P_{ss,k}$) and $E(P_{sav,k} < P_{ss,k})$ is the expectation of solar PV power below $P_{ss,k}$.

In case of the underestimation of k^{th} solar PV system, the penalty cost is given as [31,40]:

$$\begin{aligned} C_{P_s,k}(P_{sav,k} - P_{ss,k}) &= K_{P_s,k}(P_{sav,k} - P_{ss,k}) \\ &= K_{P_s,k} * f_s(P_{sav,k} > P_{ss,k}) * \\ &\quad [E(P_{sav,k} > P_{ss,k}) - P_{ss,k}] \end{aligned} \quad (31)$$

where $K_{P_s,k}$ is a coefficient represents the penalty cost pertaining to k^{th} solar PV system, $f_s(P_{sav,k} > P_{ss,k})$ is the probability of solar power surplus than the scheduled power ($P_{ss,k}$) and $E(P_{sav,k} > P_{ss,k})$ is the expectation of solar PV power above $P_{ss,k}$. As explained in Section 3.2.2, the total cost of solar PV plants (C_T^{PV}) consists of three terms (direct, underestimation and overestimation cost) and it can be given as follow [31,40]:

$$C_T^{PV} = \sum_{k=1}^{N_{PV}} C_{s,k}(P_{ss,k}) + C_{P_s,k}(P_{sav,k} - P_{ss,k}) + C_{R_s,k}(P_{ss,k} - P_{sav,k}) \quad (32)$$

147 where N_{PV} is the number of the solar PV plants.

148 4. Proposed EO

149 4.1. Inspiration and mathematical model

The main inspiration for this algorithm is the dynamic mass balance equation which describes the conservation of mass which enters, leaves or generates in a control volume. This equation is a first-order ordinary differential equation and it is described as following [35]:

$$V \frac{dC}{dt} = QC_{eq} - QC + G \quad (33)$$

where $V \frac{dC}{dt}$ is the rate of change of mass in volume, (V), C is the concentration inside the volume (V), V is the control volume, Q is the volumetric flow rate into and out of the control volume, C_{eq} is the concentration at an equilibrium state.

After reaching the steady equilibrium state of equation (33) that is reformulated as a function of $\left(\frac{Q}{V}\right)$ which is called turnover rate $\left(\lambda = \frac{Q}{V}\right)$. The following equations are derived from equation (33) to solve for (C) as a function of time (t) [35]:

$$\frac{dC}{\lambda C_{eq} - \lambda C + \frac{G}{V}} = dt \quad (34)$$

$$\int_{C_0}^C \frac{dC}{\lambda C_{eq} - \lambda C + \frac{G}{V}} = \int_{t_0}^t dt \quad (35)$$

$$F = e^{-\lambda(t-t_0)} \quad (36)$$

$$C = C_{eq} + (C_0 - C_{eq})F + \frac{G}{\lambda V} (1 - F) \quad (37)$$

150 where F , t_0 is the initial start time and C_0 is the initial concentration.

151

152 The equation (37) introduces three rules for updating the concentration of each particle. The equilibrium
153 concentration is the first term which is described as one of the best-so-far solutions randomly chosen from the
154 equilibrium pool. The difference between a concentration of a particle and the equilibrium state is the second
155 term which helps particles to globally explore the domain. The final term is called the generation rate which
156 mainly acts as an exploiter or solution refiner [35].

157 4.2. The interaction between each term and the search pattern and the definition of the EO's terms

158 4.2.1. Initialization and function evaluation

Firstly, the optimization process starts with the initial population. The equation (38) describes the initial concentration process which depends on the number of particles and dimensions that initialized in the search space in a uniform random manner [35].

$$C_i^{initial} = C_{min} + rand_i (C_{max} - C_{min}) \quad (38)$$

159 where $C_i^{initial}$ is the initial concentration vector of the i th particle, C_{min} is the minimum value for the dimensions,
160 C_{max} is the maximum value for the dimensions and $rand_i$ is a random vector ranges between zero and one. After
161 that, the fitness function of the particles are evaluated and then solved to determine the equilibrium conditions.

162 4.2.2. Equilibrium pool and candidates (C_{eq})

The global optimum of EO is represented by the equilibrium state. At the beginning, no information about the equilibrium state is existed, but equilibrium candidates are identified to provide a search domain for the particles. There are five equilibrium candidates as given in equation 39. Four of them are the best-so-far particles determined during the optimization process and the last one is the arithmetic mean of the previous-mentioned four particles. The main goal of the first four candidates is to improve the exploration capability, whereas the fifth candidate enhances the exploitation [35]

$$C_{avg} = \vec{C}_{eq}(1) + \vec{C}_{eq}(2) + \vec{C}_{eq}(3) + \vec{C}_{eq}(4) \quad (39)$$

$$C_{eq,pool} = \left\{ \vec{C}_{eq}(1), \vec{C}_{eq}(2), \vec{C}_{eq}(3), \vec{C}_{eq}(4), \vec{C}_{eq}(ave) \right\} \quad (40)$$

163 4.2.3. Exponential term (F)

The exponential term (F) helps EO to have an acceptable balance between exploration and exploitation. Referring back to equation (36), the time (t) in equation (36) depends on the iteration ($Iter$) and it is described as follows [35]:

$$t = \left(1 - \frac{Iter}{Max_{iter}}\right)^{\left(a_2 \frac{Iter}{Max_{iter}}\right)} \quad (41)$$

For the purpose of convergence, t_0 in equation (10) is proposed to slow down the search speed as well as enhancing the exploration and exploitation ability of EO [35].

$$t_0 = \frac{1}{\lambda} \ln \left(-a_1 \text{sign}(\vec{r} - 0.5) [1 - e^{-\lambda t}] \right) \quad (42)$$

164 where a_1 and a_2 are constant values for controlling exploration and exploitation ability, $\text{sign}(\vec{r} - 0.5)$ is a factor
165 that determine the direction of exploration and exploitation and r is a random vector ranges between zero and
166 one.

167 4.2.4. The generation rate (G)

The generation rate aims to provide the exact solution by enhancing the exploitation ability of EO and can be described as [35]:

$$\vec{G} = \vec{G}_0 e^{-k(t-t_0)} \quad (43)$$

After assumption that $k = \lambda$, the equation of generation rate was updated as follows [35]:

$$\vec{G} = \vec{G}_0 \vec{F} \quad (44)$$

$$\vec{G}_0 = \overrightarrow{GCP} (\vec{C}_{eq} - \lambda \vec{C}) \quad (45)$$

$$\overrightarrow{GCP} = \begin{cases} 0.5r_1, & r_2 \geq GP \\ 0, & r_2 < GP \end{cases} \quad (46)$$

where r_1 and r_2 are random number between zero and one, GCP is the generation rate control parameter.

The generation rate control parameter (GCP) mainly depends on generation probability (GP) which defines the number of particles which uses generation term to update their states.

State of the art state that EO at $GP = 0.5$, EO can achieve a good balance between exploration and exploitation. The updating rule of EO is given as:

$$\vec{C} = \vec{C}_{eq} + (\vec{C} - \vec{C}_{eq}) \vec{F} + \frac{\vec{G}}{\lambda V} (1 - \vec{F}) \quad (47)$$

168 The second and third terms of equation (47) can increase variation and thus helps EO to better explore in case of
169 they have same signs or to decrease the variation and aiding EO in local searches in case of having opposite signs
170 [35].

171 4.2.5. Particle's memory saving

172 This can help each particle track with its coordinates in the space. It aids EO in exploitation capability and
173 avoids getting trapped in local minima [35].

174 5. Implementation of EO to solve the OPF problem

175 The proposed EO is applied to solve OPF problem including wind and solar PV generation units. The
176 following pseudo code explains the steps of the application of EO for OPF problem.

- 177 1. Define the control and dependent variables and their limits as well as the target objective function defined
178 in Section 2.2.
- 179 2. Collect and read the input data of the power system under test such as data of transmission lines,
180 transformers, shunt VAR compensator, loads and generation units.
- 181 3. Calculate the estimated output power of solar PV and wind power generation units as defined and explained
182 in Section 3.
- 183 4. Initialize the particle's populations.
- 184 5. Assign a large number to the fitness of equilibrium candidates and let $a1=2$; $a2=1$; $GP=0.5$.
- 185 6. Do the main while loop as following [35]:
- 186 (a) While (current iteration (Iter) < maximum number of iteration (Max-iter))
- 187 (b) For $i=1$: particles' number (n)
- 188 (c) Find the fitness value of the i_{th} particle
- 189 i. If fitness (C_i) < fitness (C_{eq1}) then
- 190 Substitute (C_{eq1}) with (C_i) and fitness (C_{eq1})
191 with fitness (C_i)
- 192 ii. Else if fitness (C_i) > fitness (C_{eq1}) & fitness (C_i) < fitness (C_{eq2}) then
- 193 Substitute (C_{eq2}) with (C_i) and fitness (C_{eq1})
194 with fitness (C_i)
- 195 iii. Else if fitness (C_i) > fitness (C_{eq1}) & fitness (C_i)
196 > fitness (C_{eq2}) & fitness (C_i) < fitness (C_{eq3}) then
197 Substitute (C_{eq3}) with (C_i) and fitness (C_{eq3})
198 with fitness (C_i)
- 199 iv. Else if fitness (C_i) > fitness (C_{eq1}) & fitness (C_i) > fitness (C_{eq2}) & fitness (C_i) > fitness (C_{eq3}) &
200 fitness (C_i) < fitness (C_{eq4}) then
201 Substitute (C_{eq4}) with (C_i) and fitness (C_{eq4}) with fitness (C_i)
- 202 (d) End (if)
- 203 (e) End (for)
- 204 7. Find the \vec{C}_{avg} according to equation (39).
- 205 8. Construct the equilibrium pool according to equation (40) [35].
- 206 9. In case of the current iteration >1, accomplish memory saving [35].
- 207 10. Assign t according to equation (41).
- 208 11. Do the second for loop as following:
- 209 For $i=1$: particles' number
- 210 (a) Select one candidate from the equilibrium pool randomly.
- 211 (b) Create the two random vector (λ and r).
- 212 (c) Construct F , GCP , G_0 and G according to the equation (36), equation (46), equation (45) and
213 equation (44), respectively [35].
- 214 (d) Update the concentration C according to equation (47)/
- 215 End the second for loop.
- 216 12. Increase the current iteration by one.
- 217 13. End the main while loop.
- 218 14. Extract and analysis of the results.

222 6. Results and Discussion

223 The performance and effectiveness of the EO is verified for solving OPF problem by carrying out 20
224 independent test trial runs for all cases discussed in Section 2.2. The EO [35] and other five metaheuristic
225 optimization techniques: MFO [43], TACPSO [44], AGPSO1 [44], TLBO [45] and MPSO [44] have been tested
226 on four power test systems given in Section 6.1 . All these optimization techniques are implemented on 2.8-GHz
227 i7 PC with 16 GB of RAM using MATLAB 2017.

228 The number of iteration, population size ,testing ranges and other parameters of the optimization methods are
 229 given in Table 3.

230

Table 3. Control parameters values for optimization methods.

| Algorithm | Parameters | Values |
|--------------|--|-------------------------------------|
| MPSO [44] | Inertia coefficient (w) | decreasing linearly from 0.9 to 0.4 |
| | Number of search agents | 50 |
| | Maximum number of iteration | 100 |
| | Udapping factor (C1,C2) | Described in [44] |
| | Acceleration coefficient (c1,c2) | c1=1, c2=2 |
| TLBO [45] | Teaching factor | Selected randomly [1,2] |
| | Population size | 50 |
| | Maximum number of iteration | 100 |
| TACPSO [44] | Inertia coefficient (w) | decreasing linearly from 0.9 to 0.4 |
| | Number of search agents | 50 |
| | Maximum number of iteration | 100 |
| | Udapping factor (C1,C2) | Described in [44] |
| | Acceleration coefficient (c1,c2) | c1=1, c2=2 |
| MFO [43] | Population size | 50 |
| | Maximum number of iteration | 100 |
| | Shape constant (b) | 1 |
| AGPSO 1 [44] | Inertia coefficient (w) | decreasing linearly from 0.9 to 0.4 |
| | Number of search agents | 50 |
| | Maximum number of iteration | 100 |
| | Udapping factor (C1,C2) | Described in [44] |
| | Acceleration coefficient (c1,c2) | c1=1, c2=2 |
| EO [35] | Constant values for controlling exploration (a_1) | 2 |
| | Constant values for controlling exploitation (a_2) | 1 |
| | Number of search particles | 50 |
| | Maximum number of iteration | 100 |
| | Generation probability | 0.5 |

231 6.1. Description of the test power systems

- 232 • Test system 1: IEEE 30-bus system

233 The IEEE 30-bus system consists of six thermal power generators, as presented in Figure 1. The data about
 234 transmission lines, tap changing transformers, AVR compensators, limitations on generators and load
 235 voltages, active and reactive power demand are given in [46–48]. The general specifications of this system
 236 are described in Table 4.

Table 4. The general specification of all test power systems.

| Characteristics | Values and Details | | | |
|----------------------------------|-----------------------|----------------------|----------------------|----------------------|
| | Test system 1 [46–48] | Test system 2 | Test system 3 | Test system 4 |
| Buses | 30 | 30 | 30 | 30 |
| Transmission Lines | 41 | 41 | 41 | 41 |
| Limitation on generator voltage | [0.9-1.1] | [0.9-1.1] | [0.9-1.1] | [0.9-1.1] |
| Limitation on load voltage | [0.95-1.1] | [0.95-1.1] | [0.95-1.1] | [0.95-1.1] |
| Thermal power generators | 6 | 3 | 3 | 3 |
| Wind power plants | 0 | 5 | 0 | 2 |
| Solar power plants | 0 | 0 | 5 | 3 |
| Shunt VAR compensation | 9 | 9 | 9 | 9 |
| Transformer with tap ratio | 4 | 4 | 4 | 4 |
| Control Variables | 24 | 28 | 28 | 28 |
| Active and Reactive power demand | 283.4 MW ,126.2 Mvar | 283.4 MW ,126.2 Mvar | 283.4 MW ,126.2 Mvar | 283.4 MW ,126.2 Mvar |

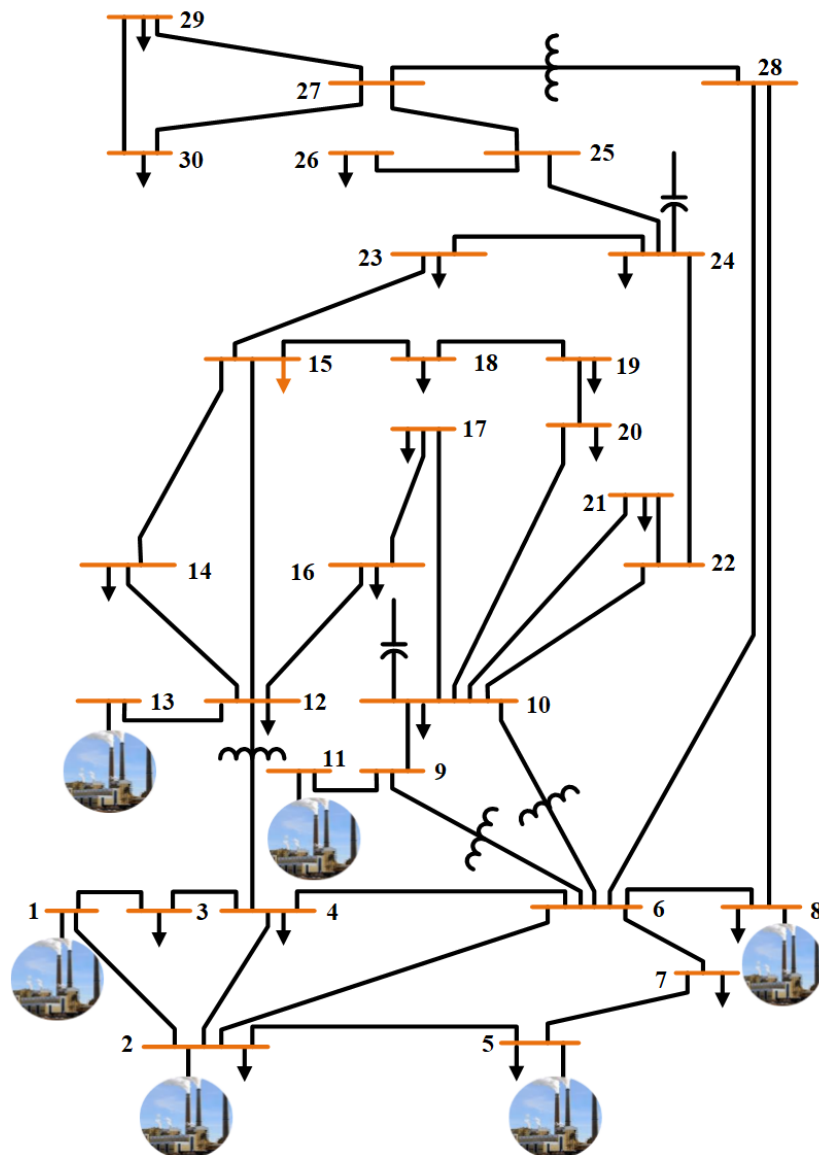

Figure 1. scenario 1: IEEE 30-bus system

237

- Test system 2: wind integrated IEEE 30-bus system

238

In this system, the IEEE 30-bus system is modified by replacing the thermal power generating units at buses 5, 11, and 13 with wind power generators. Moreover, new two wind generators have been added at buses 24, and 30, as seen in Figure 2. The objective functions defined in Section 2.2 is modified by adding the output power of wind plants ($P_w(v)$) given in Section 3. Case 3 and case 5 described in Section 2.2 are modified by adding the total cost of wind plants (C_T^w) defined in Section 3. The general specifications of this system and the data of wind power plants are given in Table 4 and Table 5, respectively.

244

- Test system 3: Solar PV integrated IEEE 30-bus system

245

This system is modified by locating solar PV generators at buses 5, 11, and 13 instead of the thermal power generators. Furthermore, two new solar power generation units are installed at buses 24, and 30, as shown in Figure 3. The objective functions defined in Section 2.2 are modified by adding the output power of solar PV plants ($P_s(G)$) given in Section 3. Case 3 and case 5 described in Section 2.2 are modified by adding the total cost of solar PV plants (C_T^{PV}) defined in Section 3. The general data of this system and solar PV plants are presented in Table 4 and Table 6, respectively.

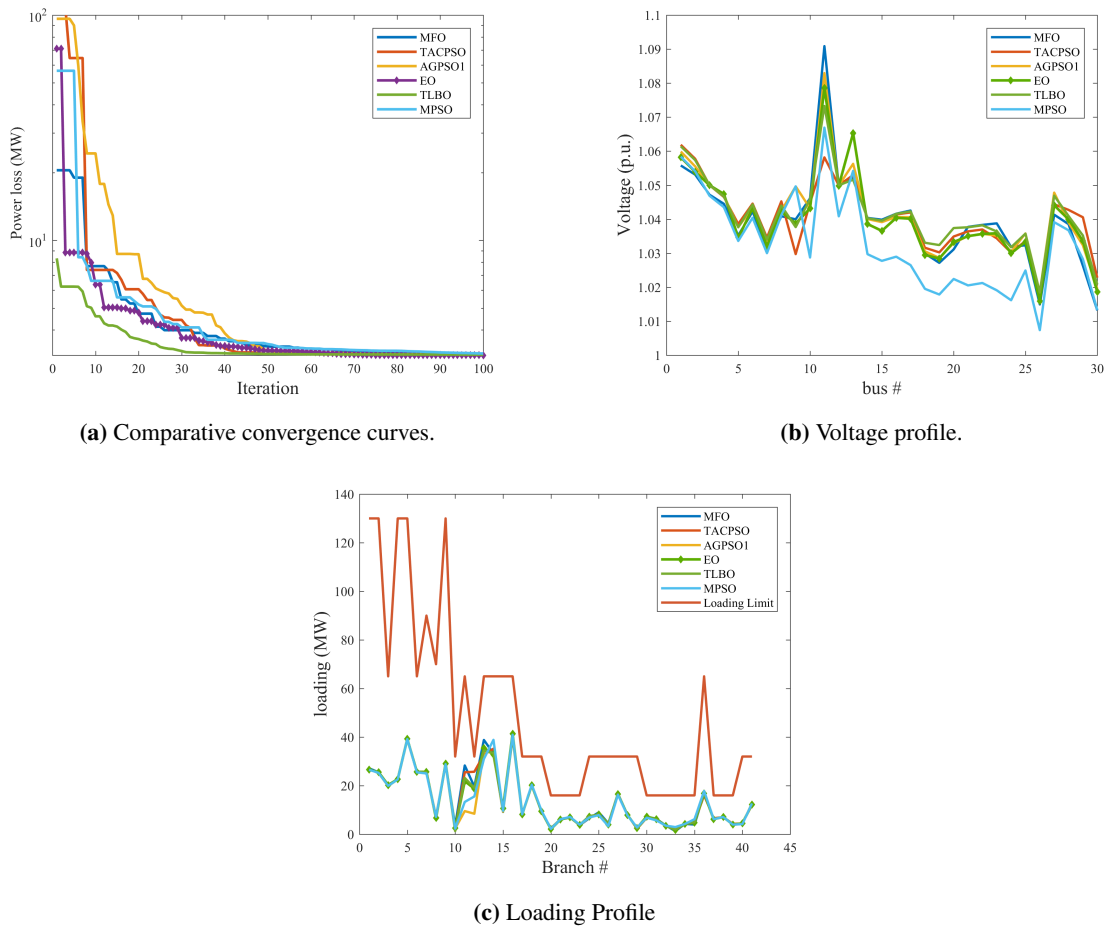

Figure 5. Comparative convergence, voltage and loading profiles for case 1 for all test systems.

271 The loss and loading profiles using EO for all test systems are given in Fig. 6. The optimal (best) results
 272 yielded by the EO method for the test system 1, test system 2, test system 3, and test system 4
 273 are tabulated in Table 10. From Fig. 6 and Table 10, it is seen that the losses of test system 2, test system 3, and test system 4
 274 reduced by 23.6%, 31.52%, and 33.32%, respectively compared to test system 1.

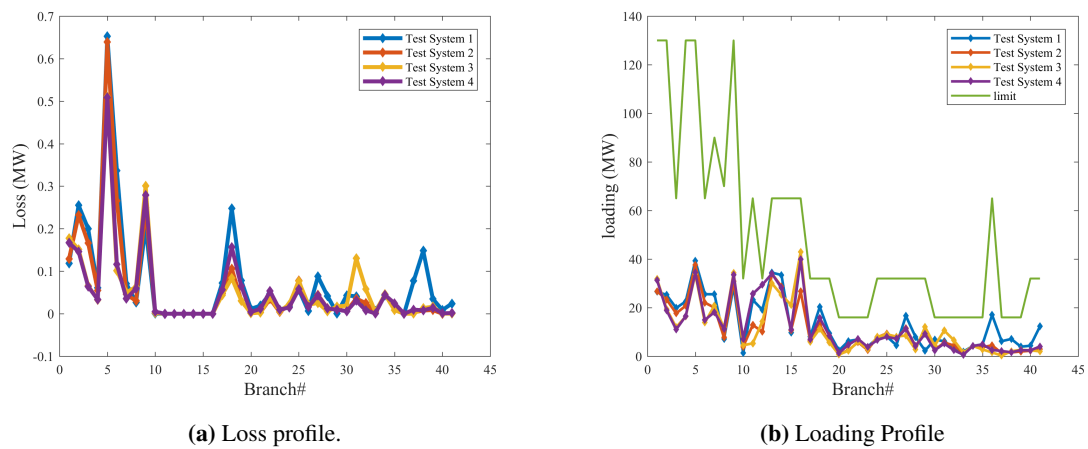

Figure 6. Loss and loading Profiles of case 1 for all test systems using EO.

| f_o (MW) | | | 3.087341565 | 2.374755583 | 2.128420834 | 2.072496662 |

275 The statistical results (the best, the worst, the mean, and the standard deviation) of the real power loss
276 for the EO and other optimization techniques are given in Table 11. As shown in Table 11, the minimum best,
277 standard deviation, and mean are resulted from the EO.

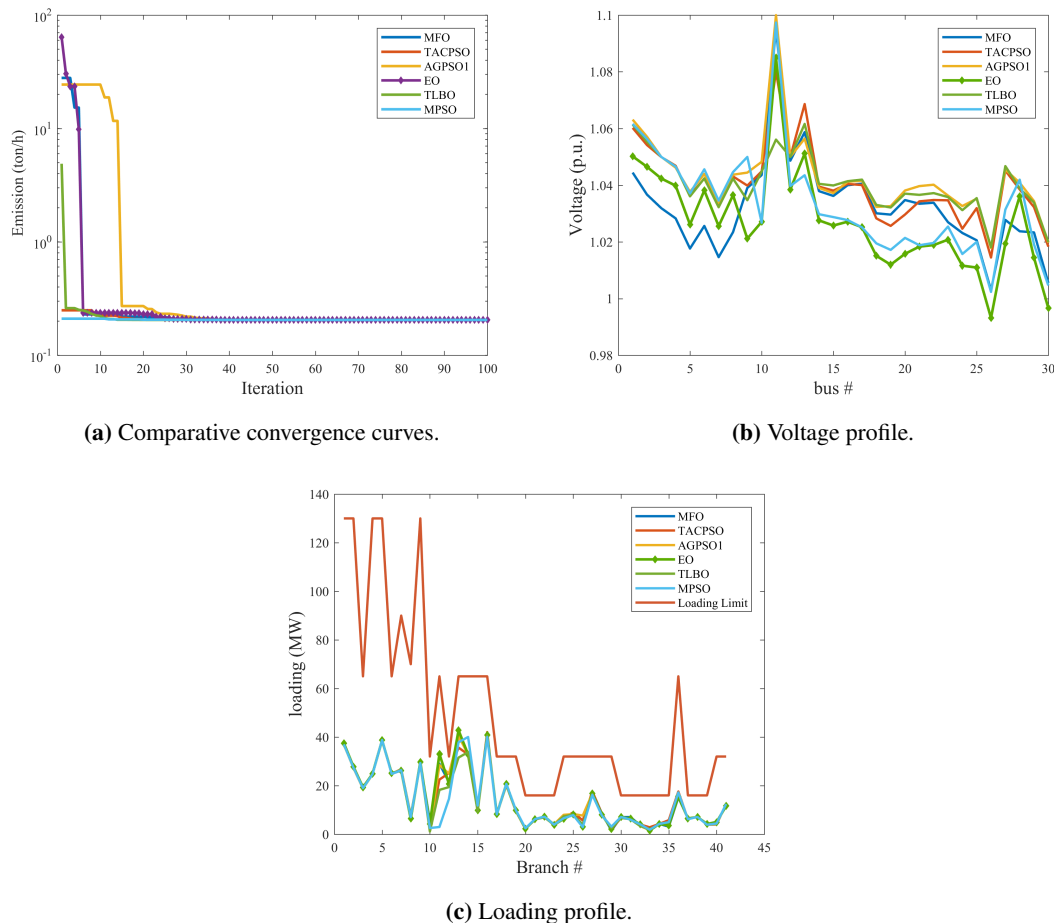

Table 11. Summary of the statistical analysis of case 1 for test system 1.

| | Best | Worst | Mean | Std dev |
|--------|----------|----------|----------|----------|
| MFO | 3.124412 | 3.469255 | 3.313791 | 0.115148 |
| TACPSO | 3.100891 | 3.495604 | 3.162984 | 0.119564 |
| AGPSO1 | 3.094156 | 3.558659 | 3.136808 | 0.175963 |
| TLBO | 3.108418 | 3.271804 | 3.200392 | 0.057571 |
| EO | 3.087342 | 3.131426 | 3.089549 | 0.013218 |
| MPSO | 3.144079 | 3.417325 | 3.202598 | 0.080901 |

278 As expected, the addition and location of the renewable energy resources in the power system have a
 279 significant impact on reducing the real power loss.

280 6.2.2. Emission Index Minimization

281 In this case, the emission index defined in section 2.2 was minimized for all test systems. Fig. 7 demonstrates
 282 the convergence characteristics, loss profiles, and loading profiles for emission minimization using EO and other
 283 methods. It can be noticed from Fig. 7a that the EO has the smoothest and speediest convergence curves in
 284 comparing with other techniques, as well as Fig.7b and Fig.7c show that there is no violation in the voltage limits
 285 of buses and loading limits of transmission lines.

**Figure 7.** Comparative convergence ,voltage and loading Profiles for case 2 for all test systems.

286 The best (optimal) results obtained using the EO for all test systems for case 2 are shown in Table 12 .As
 287 we can see from Fig. 8 and Table 12 that emission index reduced by 55.54% for test system 2, test system 3, and
 288 test system 4 compared to test system 1.

Table 12. Optimal settings of control variables for case2 for all test systems using EO.

| Parameters | Min | Max | Test system 1 | Test system 2 | Test system 3 | Test system 4 |

295 6.2.3. Minimization of the total cost of generating units

296 The comparative convergence characteristics, loading profiles, and loss profiles for test system 1 for the EO
 297 and other optimization techniques are presented in Fig.9. As observed in Fig.9, the voltage and loading profiles
 298 are kept within the acceptable ranges and the EO gives the best convergence characteristics compared to other
 299 methods. The optimal results of the EO and other techniques for test system 1 are summarized in Table 15. From
 300 Table 15, the EO leads to 800.4486\$/hr total cost of generators which is better than the total cost obtained by the
 301 other compared methods.

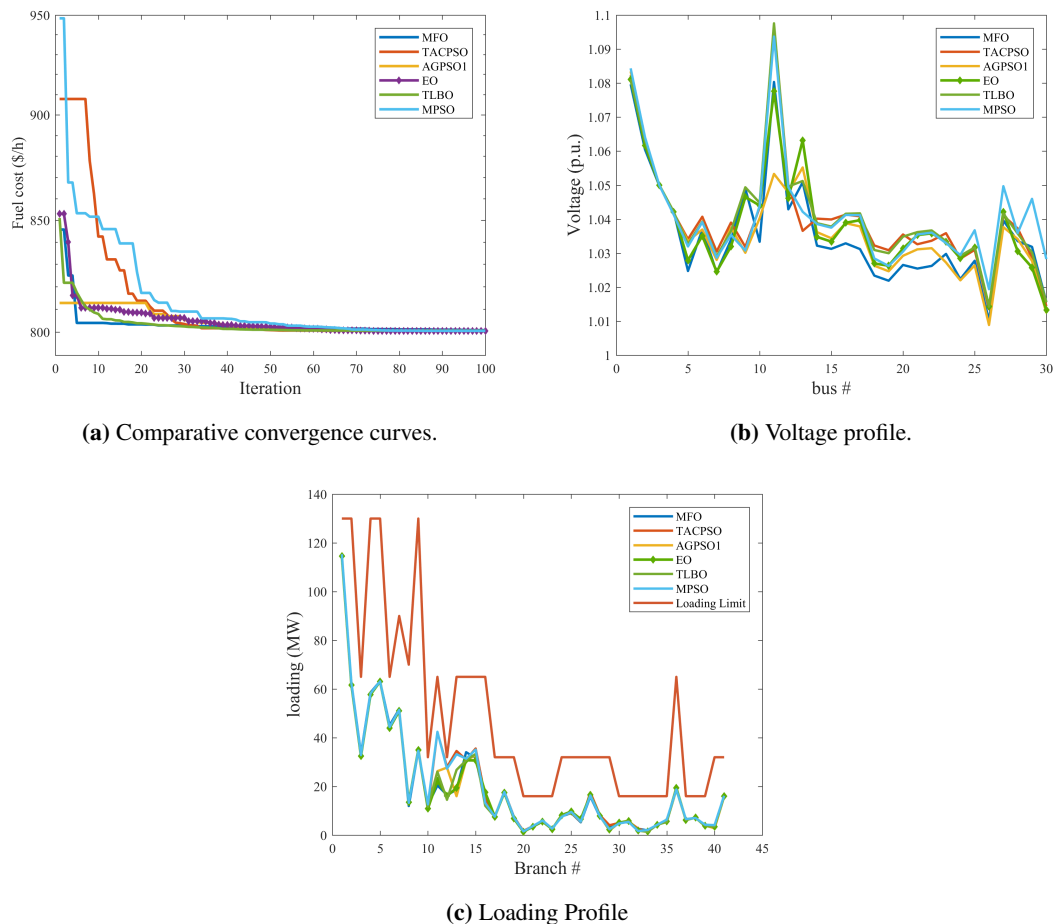

Figure 9. Comparative convergence, voltage and loading Profiles for case 3 for all test systems.

Table 15. Results of EO and other methods of case 3 for test system 1.

| | MFO | TACPSO | AGPSO1 | TLBO | EO | MPSO |
|-----------------|----------|----------|----------|-------------|----------|----------|

302

The statistical results yielded by the EO and other optimization techniques are given in Table 16.

Table 16. Summary of the statistical analysis of case 3 for test system 1.

| | Best | Worst | Mean | Std dev |
|--------|----------|----------|----------|----------|
| MFO | 800.8283 | 802.8078 | 801.5102 | 0.72899 |
| TACPSO | 800.5201 | 804.0448 | 800.6766 | 1.305504 |
| AGPSO1 | 800.5595 | 802.1145 | 800.7023 | 0.453581 |
| TLBO | 800.6162 | 802.225 | 800.8366 | 0.471362 |
| EO | 800.4486 | 800.646 | 800.4793 | 0.057894 |
| MPSO | 800.5346 | 804.6442 | 801.1155 | 1.810857 |

303 From Table 17 and Fig.10, it can be observed that the total cost of generating units for test system 2, test
 304 system 3, and test system 4 declined by 3.54%, 3.47%, and 2.91%, respectively compared to test system 1.

**Figure 10.** Total cost of generating units of case 3 for all test systems using EO.

Table 17. Optimal settings of control variables for case 3 for all test systems using EO.

305 6.2.4. Voltage Deviation Minimization

306 Fig.11 demonstrates the voltage profiles for all test systems for this case using EO. The optimal solution
 307 obtained by EO for test system 1, test system 2, test system 3, and test system 4 are tabulated in Table 18. As
 308 shown in Fig.11 and Table 18, the presence of the renewable energy resources improves the voltage profiles and
 309 reduced the voltage deviation for test system 2, test system 3, and test system 4 by 22.46% ,37.39%,and 29.61% ,
 310 respectively compared to test system 1.

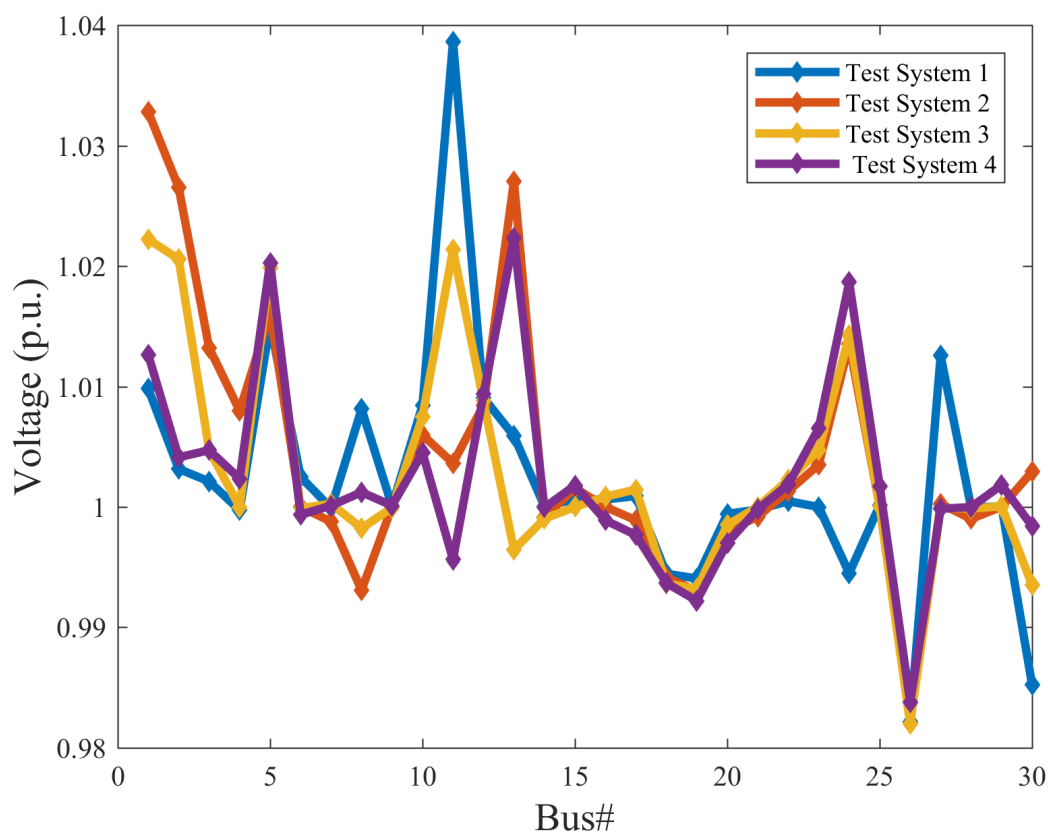

Figure 11. Voltage profiles of case 4 for all test systems using EO.

Table 18. Optimal settings of control variables for case 4 for all test systems using EO.

312 From Fig.12, the voltage and loading profiles for this case for all optimization methods obey the constraints
 313 of voltages at load buses and transmission line loading. It can be also observed that the EO convergence
 314 characteristic outperforms the convergence characteristics of other methods. The results of EO and other methods
 315 for test system 1 are given in Table 20.

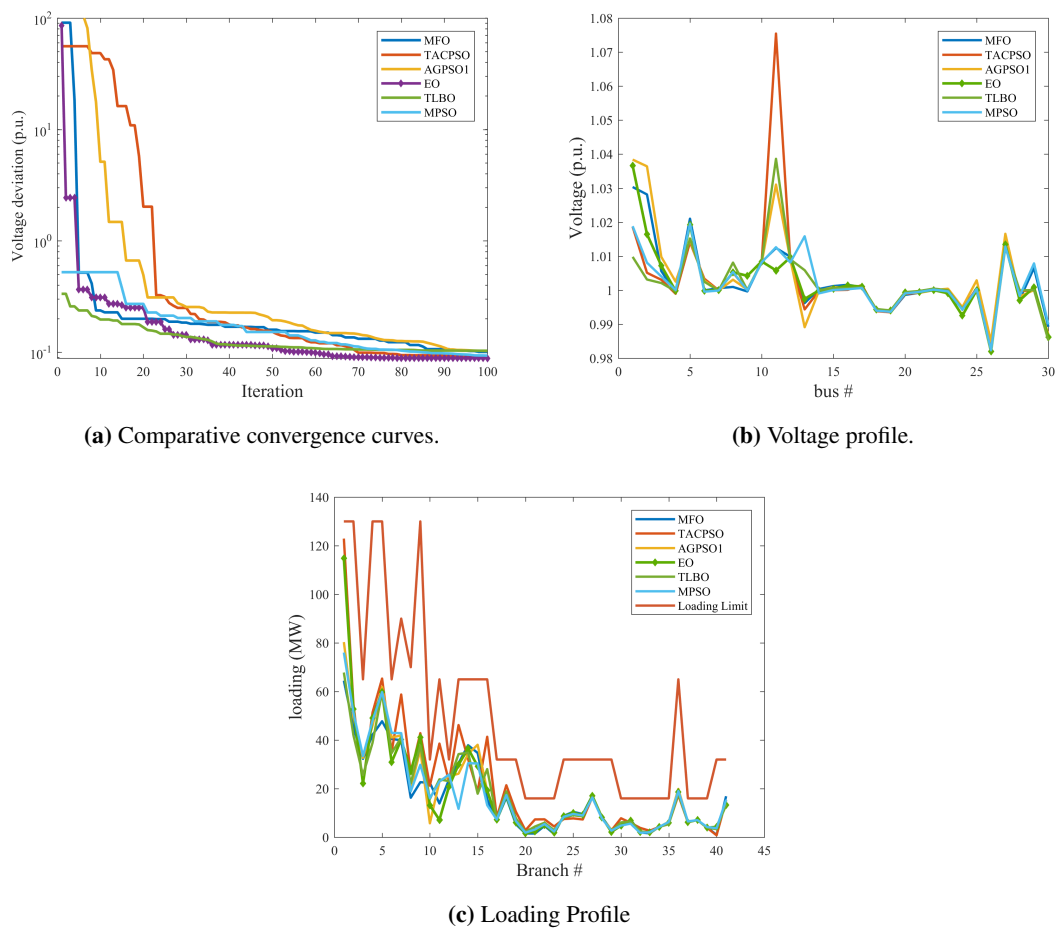

**Figure 12.** Comparative convergence, voltage and loading profiles for case 4 for all test systems.

Table 20. Results of EO and other methods of case 4 for test system 1.

316 6.2.5. Case 5: Minimization of the total cost of the generating units, voltage deviation, real power loss, and
 317 emission index

318 It is clear from Fig. 13, the EO has the best convergence characteristics compared to the other optimization
 319 algorithms and the voltage and loading profiles for all algorithms ranges within the allowable limits. The results
 320 of EO and other methods for test system 1 of this case are shown in Table 21.

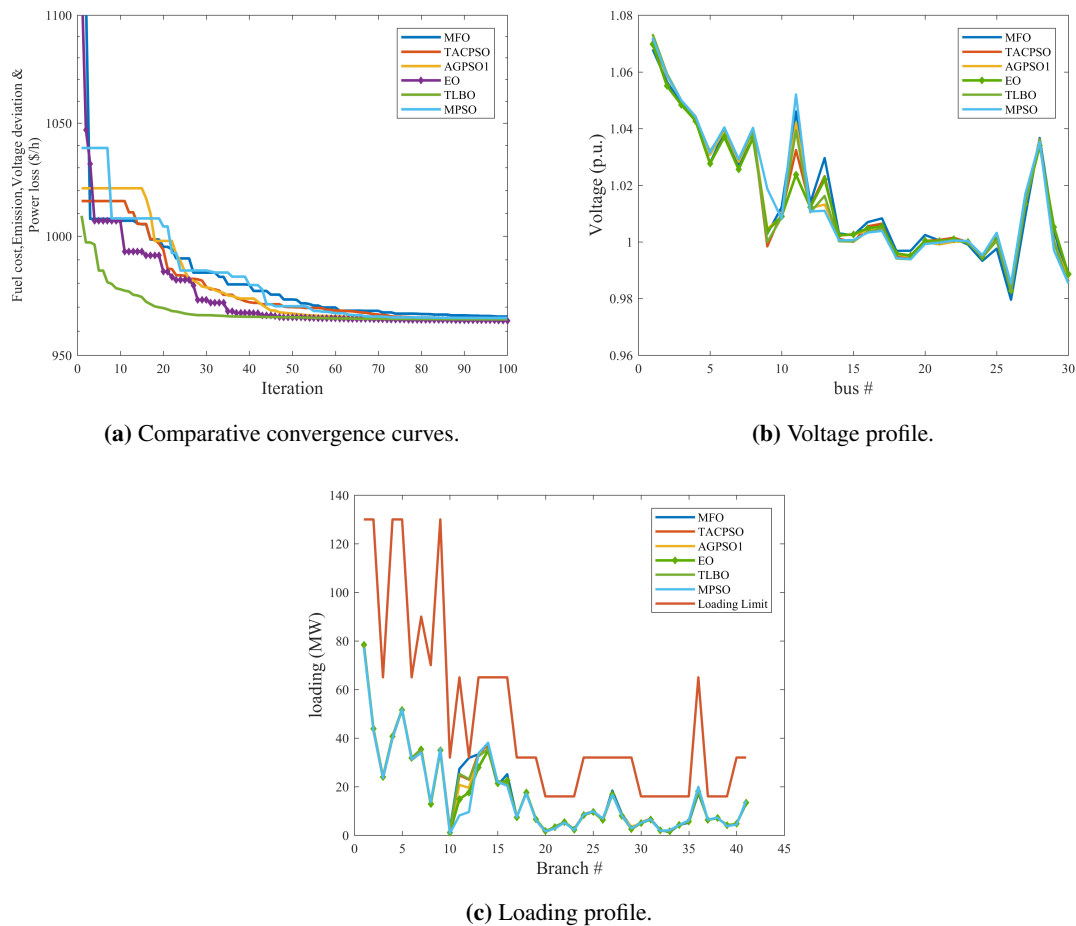

**Figure 13.** Comparative convergence, voltage and loading profiles for case 5 for all test system 1.

Table 21. Results of EO and other methods of case 5 for test system 1.

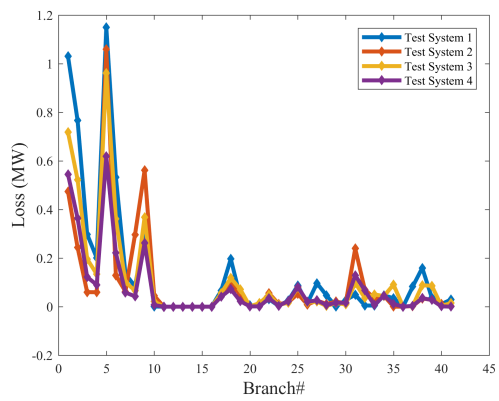

| | MFO | TACPSO | AGPSO1 | TLBO | EO | MPSO |
|-----------------|----------|----------|----------|-------------|----------|----------|
| VD (p.u.) | 0.312222 | 0.301092 | 0.2979 | 0.292001838 | 0.291525 | 0.315655 |
| FC (\$/h) | 832.131 | 833.4427 | 831.8455 | 831.251448 | 829.9924 | 833.2358 |
| P_{loss} (MW) | 5.569804 | 5.471244 | 5.542919 | 5.575077257 | 5.604236 | 5.490564 |
| E (ton/h) | 0.250434 | 0.249973 | 0.251339 | 0.252691258 | 0.253454 | 0.249919 |
| f_o (\$/h) | 965.9816 | 964.8825 | 964.8211 | 964.8363202 | 964.2232 | 965.4054 |

321 The statistical analysis of the EO and other methods for test system 1 are given in Table 22. As shown in
 322 table, the EO gives the minimum best, median and standard deviation.

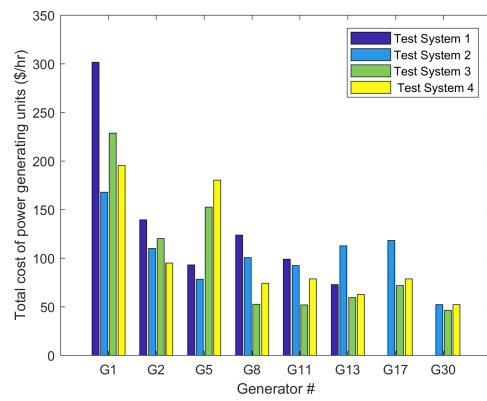

Table 22. Summary of the statistical analysis of case 5 for test system 1.

| | Best | Worst | Mean | Std dev |
|--------|----------|----------|----------|----------|
| MFO | 965.9816 | 970.7178 | 968.0071 | 1.616872 |
| TACPSO | 964.8825 | 968.5757 | 965.8415 | 1.251791 |
| AGPSO1 | 964.8211 | 967.8093 | 965.6185 | 0.874411 |
| TLBO | 964.8363 | 968.0825 | 966.0087 | 1.105687 |
| EO | 964.2232 | 966.3464 | 964.5618 | 0.655197 |
| MPSO | 965.4054 | 978.9642 | 966.4455 | 4.054598 |

323 It is clear from Fig. 14 and Table 23 that the objective function for this case for test system 2, test system 3,
 324 and test system 4 dropped by 3.90%, 7.77%, and 7.84%, respectively compared to test system1. It is found from
 325 Table 23 that the real power loss for test system 2, test system 3, and test system 4 dropped by 30.94%, 20.75%,
 326 and 46.06%, respectively compared to test system1.

(a) Loss profile.

(b) Total cost of generating units.

(c) Total emission index.

(d) Voltage profiles.

Figure 14. Total cost of generating units, total emission index, voltage and loss profiles of case 5 for all test systems.

Table 23. Optimal settings of control variables for case 5 for all test systems using EO.

327 7. Conclusions

328 In this study, a novel proposed EO method has been successfully applied to solve single and multi-objective
329 OPF with integrated wind turbines and solar PV generators. Its performance and effectiveness were evaluated on
330 four power system, namely: IEEE 30-bus system, wind integrated IEEE 30-bus system, solar PV integrated IEEE
331 30-bus system, and hybrid wind and solar PV integrated IEEE 30-bus system. Realistic models for the wind
332 turbines and solar PV systems have been proposed and thus real power outputs of wind turbines and solar PV
333 power plants have been accurately forecasted. Therefore, correct and efficient decision can be taken for inclusion
334 the wind turbines and solar PV power plants in the proper locations. The simulation and statistical results indicate

335 and approve that the EO[35] method outperforms other optimization techniques ,namely: TLBO [45], MPSO
336 [44], MFO [43], AGPSO1 [44], and TACPSO [44] .Our research has highlighted the importance of the proper
337 locations of the renewable energy resources on improving the objective functions of OPF problem. Furthermore,
338 adding wind turbines and solar PV play an integral role in enhancing the performance of the standard IEEE
339 30-bus system .For example, they significantly reduce the fuel cost and emission of the conventional power
340 generators ,as well as minimize real power loss and voltage deviation .

341 **Author Contributions:** Both authors have made equal contributions to this work.

342 **Funding:** This research received no external funding.

343 **Conflicts of Interest:** The authors declare no conflict of interest.
