**Abstract:** The commonly-used large-scale knowledge bases have been facing challenges in open domain question answering tasks which are caused by the loose knowledge association and weak structural logic of triplet-based knowledge. To find a way out of this dilemma, this work proposes a novel metaknowledge enhanced approach for open domain question answering. We design an automatic approach to extract metaknowledge and build metaknowledge network from Wiki documents. For the purpose of representing the directional weighted graph with hierarchical and semantic features, we present an original graph encoder GE4MK to model the metaknowledge network. Then a metaknowledge enhanced graph reasoning model MEGr-Net is proposed for question answering, which aggregates both relational and neighboring interactions comparing with R-GCN and GAT. Experiments have proved the improvement of metaknowledge over main-stream triplet-based knowledge. We have found that the graph reasoning models and pre-trained language models also have influences on the metaknowledge enhanced question answering approaches.

**Keywords:** metaknowledge; graph modeling; question answering; graph neural networks; knowledge graph; knowledge graph

## 0. Introduction

Open domain Question Answering (QA) is a type of language tasks, which asks models to answer the factoid questions described in natural language. Recently, large-scale Knowledge Bases (KBs), such as DBpedia[1], FreeBase[2], and YAGO[3], have proven to be effectively applied on the open domain QA tasks. While the idea of this kind of triplet-based knowledge is an adaptive variation of complex network, which inherits its long-tail effect in the QA tasks due to triplets' sparsity and lack of logical association[4].

Obviously, the simplified triplet-based knowledge is not exactly as same as the knowledge in human beings' perception. Knowledge in human minds is a complex of hierarchical, structured, and systematized elements which has strongly logical or topological associations, especially presented in structure or sequence, while the very knowledge that exists in commonly-used knowledge bases is simplified presented as *entity-relation* triplets.

When most of existing works focus on triplet-based KBs, more general denition about KBs and a various usages of KBs such as conceptual graph[5] and event evolu-

tionary graph[6] have been proposed to improve the QA approaches and other tasks' performance from different perspective.

However, just like the taxonomy construction manufactured within the conceptual graph, the content of the documents and webs was hopefully to be explicitly represented through metadata in order to enable contents-guided search and other downstream tasks. But the knowledge in the real world could hardly be strictly partitioned into the hand-craft-built or evolutionary taxonomy[5] with accurate levels and divisions hierarchically. Since the taxonomy construction is tough, cumbersome and new knowledge always led to new partitioning and reconstruction problems, it is intuitively vital to consider another flexible presentation for the hierarchical knowledge.

To match human's natural intuition of knowledge, different from the strictly designed and partitioned conceptual graph, our previous work[7] introduces the concept of metaknowledge[8] into knowledge engineering research. Similar to the metadata, metaknowledge is a kind of graph data. It is structural representation of knowledge and knowledge with fine-grained and hierarchical characteristics, but the knowledge triplets are weighted directional in hierarchy based on the structured information given by the original sources.

Firmly based on the open domain QA task, in this work, we have: (1) designed an automatic approach for generating metaknowledge and building metaknowledge network from Wiki documents; (2) proposed an original graph encoder GE4MK for modeling the metaknowledge (network) to the weighted directional graph with hierarchical and semantic features; (3) presented a graph reasoning model MEGr-Net for metaknowledge enhanced open domain QA; (4) carried out experiments for verifying the improvement of our metaknowledge-based open domain QA approach with triplet-based approaches.

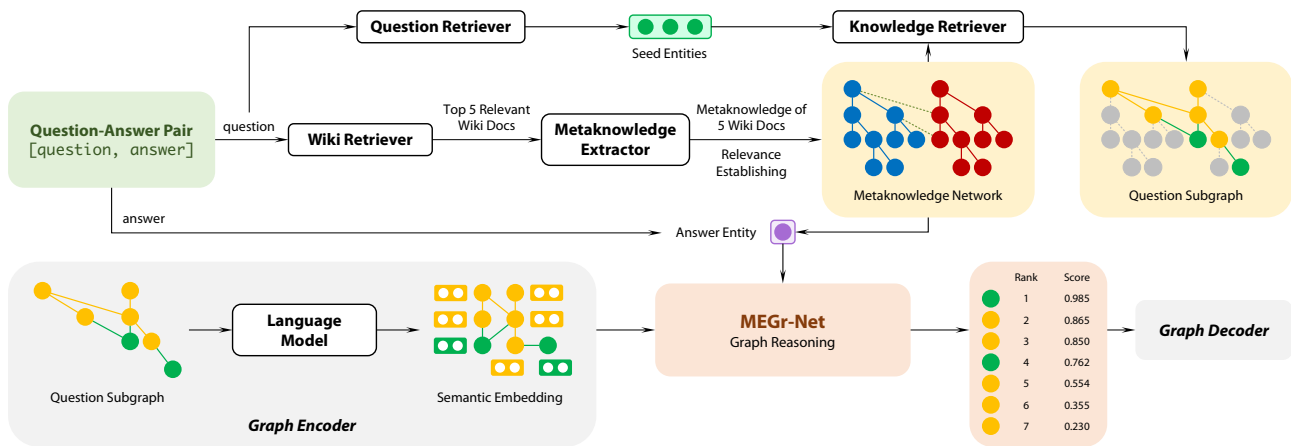

## 1. Related Work

### • Knowledge Base Question Answering (KBQA)

The goal of KBQA is to use large-scale knowledge bases to answer questions described in natural language (natural questions), and the primary task is to understand and extract the actual semantic connotation from natural questions, then retrieve entities or relations in knowledge bases as the answers. Presently, there are two pipelines in KBQA: the Semantic-Parsing-based (SP-based) pipeline and the Information-Retrieval-based (IR-based) pipeline[4,9]. The early-days SP-based approaches mainly rely on hand-craft-established rules[10] and supervised learning[11]. Recently, The convolutional neural network[12], attention mechanism[13], graph2seq model[14], and reinforcement-learning-based approaches[15,16] are also used in SP-based KBQA.

With the rapid development of knowledge representation learning, the IR-based approaches have now become the mainstream in KBQA[17–20]. These approaches extract information from questions, retrieve the information in knowledge bases (knowledge graphs), and then use graph reasoning models to decide which entities or relations are the answers. Basically, the steps of the IR-based approaches are: (1) Getting the seed entities from the given natural question, retrieving seed entities in the knowledge base and then building question subgraph, in which the entities and relations are all the semantically associated with the seed entities. (2) Representing the given question with question encoder, which analyzes semantic features in the question and outputs a commanding vector (question embedding) for reasoning. (3) Reasoning with embedding of the given question and the question subgraph got in step (1) and (2), then getting the probability whether it is the answer for each entity in the question subgraph. (4) Ranking the probability sequence and deciding the most-likely answer entity.

Meanwhile, it has been quite unsatisfying when using triplet-based KBs alone in complex KBQA tasks like multi-hop question answering, and the problem that triplet-based knowledge lacks of structural logicity has become apparent. In order to make up for the capacity limitation of the existing KBs, a common practice is to introduce

**Figure 1.** An overview of our approach. There are basically four steps of our approach: (a) generating metaknowledge; (b) building metaknowledge network; (c) graph modeling and encoding; (d) graph reasoning.

heterogeneous data like documents to enrich the semantic information, which is referred to as Document-based Question Answering (DbQA). Ref.[21] proposes a question answering model combining FreeBase and Wikipedia documents. In order to improve the QA effectiveness in the case of insufficient capacity of knowledge base, Ref.[22] proposes an early-fusion approach to link the entities of knowledge base with the text in the document. In the multi-hop QA task, Ref.[23] carries out multi-grained document modeling, constructs hierarchical graph, and demonstrates graph reasoning and answer prediction through Machine Reading Comprehension (MRC) method.

The inspiration of the above works is that, the defects of knowledge base can be made up for by improving the semantic parsing ability and introducing heterogeneous data represented by documents, with the intention of continuously improving the effectiveness of question answering.

- **Graph Neural Networks for Graph Embedding**

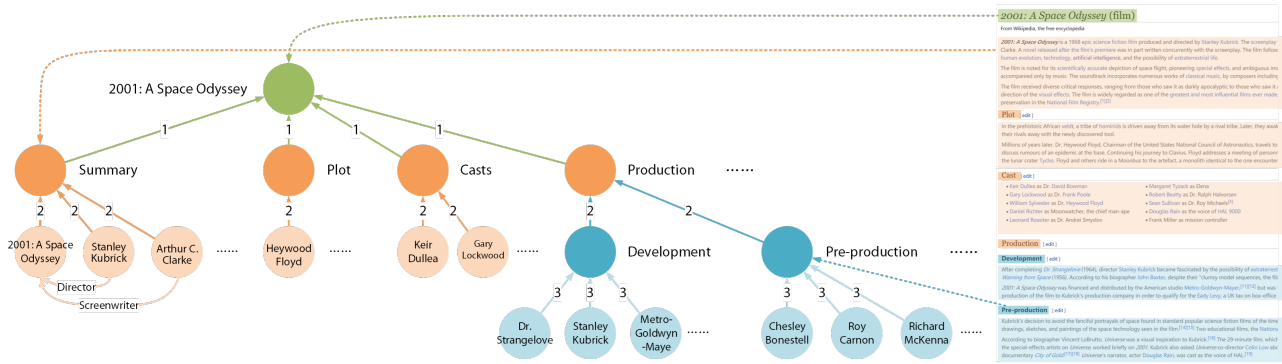

The purpose of graph embedding is to represent the nodes, edges or subgraphs of a graph as low-dimensional vectors through neural networks. Classical graph embedding approaches based on graph representation learning include DeepWalk, node2vec and LINE, etc. Recently, Graph Neural Networks (GNNs) have become the new tools for graph embedding. Ref.[24] proposes the Graph Convolutional Network (GCN) model and applies it to the self-supervised node classification task. On the basis of GCN, Ref.[25] models the complex relational data in the knowledge graph and puts forward the R-GCN (relational GCN) model, which uses two different parameters matrices for vertices and edges (relations). Inspired by the attention mechanism in Transformers [26], Ref.[27] proposes the Graph Attention Network (GAT) to comprehensively consider the influence of neighboring vertices on graph embedding.

The approaches for embedding relational graph proposed in R-GCN and the multi-heads attention mechanism in GAT provide enlightenment on how to realize the representation of graph data with complex relations and semantic information such as metaknowledge and metaknowledge networks.

## 2. Approach

Since the metaknowledge is different from the triplet-based knowledge, this work proposes an approach (Figure 1) to make metaknowledge available for question answering.

Essentially, metaknowledge is a special type of hierarchical graph, it generally has two different types of vertices and edges: (a) **Hierarchical vertices and edges**. The hierarchical vertices include multiple levels of section titles in documents, denoted as  $V_H$ , and the hierarchical edges represent a special relation *hierarchical belonging*, denoted

**Figure 2.** An example of metaknowledge extracted from Wiki documents. The number on the arrows indicates the hierarchical levels of the relations, which are also the weight of edges.

as  $E_H$ . **(b) Semantic vertices and edges**, which are actually the entities and relations extracted from documents, denoted as  $V_S$  and  $E_S$ .

So the metaknowledge extracted from document  $i$  is denoted as:

$$M_i = \{V_{Hi} \cup V_{Si}, E_{Hi} \cup E_{Si}\}. \quad (1)$$

Meanwhile,

$$V_{Hi}^L \xrightarrow{E_{Hi}} V_{Hi}^{L-1}, V_{Si}^L \xrightarrow{E_{Si}} V_{Hi}^L, v_{Sij}^L \xrightarrow{E_{Si}} v_{Sik}^L, \quad (2)$$

where  $\xrightarrow{E_{Hi}}$   $V_{Hi}$  denotes the *hierarchical belonging* relation in the document structure,  $L$  denotes the hierarchical level of the vertices,  $v_{Sij}^L, v_{Sik}^L \in V_{Si}^L$ .

### 2.1. Generating Metaknowledge

Giving a question  $q$  described in natural language, this work uses Wiki retriever proposed in DrQA[21] to get the top 5 relevant Wiki documents  $\mathcal{D}_q = \{D_1, \dots, D_5\}$ . For each document  $D_i$ , we use open source NLP models to extract the entities and relations (referred to as **metaknowledge semantic elements** in this work) in paragraphs.

In this work, we transform the HTML script of each Wiki document web page into hierarchical XML files by parsing the HTML labels, such as  $\langle h1 \rangle$ ,  $\langle h2 \rangle$ ,  $\langle h3 \rangle$ ,  $\langle div \text{ id}="toc" \dots \rangle$ ,  $\langle p \rangle$ , which represent the title, section titles, summary or paragraphs (referred to as **metaknowledge hierarchical elements** in Ref.[7]).

Suppose Wiki document  $D_i = \{P_i, C_i\}$ , where  $P_i = \{p_{i1}, p_{i2}, \dots, p_{i|P_i|}\}$  denotes the paragraphs set in the document  $D_i$  ( $|P_i|$  is the total number of paragraphs);  $C_i = \{c_{i1}, c_{i2}, \dots, c_{i|C_i|}\}$  denotes the hierarchical elements, then each paragraph  $p_{ij}$  ( $j \in |P_i|$ ) hierarchically belongs to their upper hierarchical elements  $c_{ik}$  ( $k \in |C_i|$ ) (e.g. section titles). Further, this work extracts entities and relations paragraph by paragraph using Stanza[stanza] and OpenNRE[opennre], then link the metaknowledge semantic elements to hierarchical elements with document structure (Figure 2).

Each document metaknowledge is saved as a JSON file converted from Python dictionary (denoted as metaknowledge dictionary), its key-value structure is as follow:

```
Dict:{
|- "Entities": {
| |- "0": {
| | |- "ENT_ID": 'ENT_1'
| | |- "type": 'title'
| | |- "content": '2001: A Space Odyssey'
| | |- "weight": -1
| | |- "title": '2001: A Space Odyssey'
| | |- "up_ID": 'ENT_1' }
| |- ...
```

```

|   |- "30": {
|     |- "ENT_ID": 'ENT_31'
|     |- "type": 'PERSON'
|     |- "content": 'Stanley Kubrick'
|     |- "weight": 2
|     |- "title": '2001: A Space Odyssey'
|     |- "up_ID": 'ENT_25' } }
|
| - "Relations": {
|   |- "0": {
|     |- "REL_ID": 'REL_1'
|     |- "head_ID": 'ENT_5'
|     |- "tail_ID": 'ENT_1'
|     |- "type": 'Hierarchical Belongs'
|     |- "weight": -1 }
|   |- ...
|   |- "16": {
|     |- "REL_ID": 'REL_17'
|     |- "head_ID": 'ENT_25'
|     |- "tail_ID": 'ENT_18'
|     |- "type": 'performer'
|     |- "weight": 2 } }

```

The weights of hierarchical vertices and edges are set as negative, which are the opposite number of their level, for instance, weights of the 1st-level hierarchical vertices are -1, the 2nd-level vertices are -2. In contrast, the semantic vertices and edges are set as positive, which are the exact level of the hierarchical vertices they belong to.

For different **relatively-weighted** hierarchical graph.

The denotations of keys in metaknowledge dictionary are shown in Table 1.

**Table 1.** Denotations of keys in metaknowledge dictionary.

Entities		Relations	
ENT_ID	Entity ID	REL_ID	Relation ID
type	Entity Type	type	Relation Type
content	Entity Textual Content	head_ID	Head Entity ID
weight	Entity Weight	tail_ID	Tail Entity ID
title	Document Title	weight	Relation Weight
up_id	Upper Hierarchical Entity ID		

## 2.2. Building Metaknowledge Network

For documents  $\mathcal{D} = \{D_1, D_2, \dots, D_N\}$ , the semantic association between  $D_i$  and  $D_j$  is denoted as  $\mathcal{R}_{ij}$ , then the metaknowledge network built on  $\mathcal{D}$  is denoted as  $\mathcal{N} = \cup_{i,j \in N} \{M_i \xleftrightarrow{\mathcal{R}_{ij}} M_j\}$ . When building metaknowledge network from document metaknowledge, to avoid the loss of hierarchy caused by semantic entity fusion, this work only establishes semantic association between hierarchical vertices.

Suppose  $v_{H1} \in M_1, v_{H2} \in M_2$  are two semantically associated hierarchical vertices in document metaknowledge  $M_1$  and  $M_2$ , their textual embedding vectors are:

$$emb_{H1} = LM(text_{v_{H1}} + text_{title1}), emb_{H2} = LM(text_{v_{H2}} + text_{title2}). \quad (3)$$

where  $LM(\cdot)$  denotes the pre-trained language models (PLMs), such as BERT[28], RoBERTa[29], XLNet[30], etc.

Then we use cosine similarity to calculate the semantic association between two hierarchical vertices:

$$\mathbf{IF} \quad \text{cosinesim}(emb_{H1}, emb_{H2}) \geq \text{tolerance}, \quad \mathbf{THEN} \quad v_{H1} \xrightarrow{r_{H1H2}} v_{H2}. \quad (4)$$

To decide the appropriate tolerance threshold, we use BERT as the PLM. Taking "South Africa" as the keyword, this work retrieves 10 relevant Wiki documents using Wikipedia Search. Through hand-craft selection, 78 groups of associated metaknowledge hierarchical vertices are picked up. The cosine similarity of semantic embedding in each group is encoded by BERT. Then the statistical results of this test are shown in Figure 3.

**Figure 3.** Test to decide metaknowledge association tolerance.

Figure 3 indicates that the cosine similarity between associated hierarchical vertices is basically in the range of  $[0.7, 0.9]$ , therefore, this work adopts  $\text{tolerance} = 0.7$ .

Meanwhile, we use S-MART<sup>1</sup> to obtain relevant entities to  $q$ , called seed entities  $\mathcal{S}_q = \{s_1, \dots, s_{|\mathcal{S}_q|}\}$ . Then a retrieval starts in order to find the directly connected semantic vertices  $V_{S_q}$  and hierarchical vertices  $V_{H_q}$ , the latter extends to the top level hierarchical vertex (see also Knowledge Retriever in Figure 1). Then we get the question subgraph  $\mathcal{G}_q$ :

$$\begin{aligned} \mathcal{G}_q &= \{\mathcal{V}_q, \mathcal{R}_q\}, \mathcal{V}_q = \{\mathcal{S}_q, V_{S_q}, V_{H_q}\}, \\ s_i &\xrightarrow{r_{Sij}} v_{Sj}, s_i^L \xrightarrow{r_{Hij}} v_{Hj}^L \xrightarrow{r_{Hjk}} v_{Hk}^{L-1} \leftarrow \dots \rightarrow v_{H0}^0, s_i \in \mathcal{S}_q, v_{hj,k} \in V_{H_q}. \end{aligned} \quad (5)$$

### 2.3. Metaknowledge Encoding

In this work, we propose a Graph Encoder for Metaknowledge (GE4MK) to encode the text-described document metaknowledge. For document metaknowledge  $M_i = \{V_{Hi} \cup V_{Si}, E_{Hi} \cup E_{Si}\}$ , the features of each vertex  $v_j \in V_{Hi} \cup V_{Si}$  could be divided into three parts: (1) the semantic features of  $v_j$  itself, including its textual content  $v_{cj}$  and its entity type  $v_{tj}$ ; (2) the hierarchical features of  $v_j$  itself, including the semantic features  $v_{uj}$  of the upper hierarchical vertex that  $v_j$  belongs to, and the title's semantic features  $t_j$ ; (3) the semantic features  $r_{j1}, r_{j2}, \dots, r_{jk}$  of relations between  $v_j$  and its  $k$  nearest 1-hop neighboring vertices.

Consequently, the vertex features  $\mathbf{h}_j$  of  $v_j$  can be described as:

$$\mathbf{h}_j = \left[ f_s(v_{cj}, v_{uj}, t_i) \parallel f_t(v_{tj}) \parallel f_r(r_{j1}, r_{j2}, \dots, r_{jk}) \right], \quad (6)$$

where

$$v_{cj} = LM(\text{text}_{cj}), v_{uj} = LM(\text{text}_{uj}), t_i = LM(\text{text}_{title}), \quad (7)$$

The output of these PLMs is a  $\lambda$ -dimensional dense semantic vector. The  $f_s$  in Eq.3 indicates a 2-layers MLP, which transforms the concatenation of  $[v_{cj}, v_{uj}, t_i]$  from  $\mathbb{R}^{3\lambda}$  to  $\mathbb{R}^{3D}$ ,  $D$  indicates the dimension of feature space which is manually set depending on the using PLM; for instance, in this work we set  $D = 1000$ .  $f_t : \mathbb{R}^{|\tau|} \rightarrow \mathbb{R}^{D/2}$  and  $f_r : \mathbb{R}^{k|\mathcal{R}|} \rightarrow \mathbb{R}^{kD}$  are linear transformations, where  $|\tau| = 9$  in Stanza and  $|\mathcal{R}| = 80$  in OpenNRE<sub>Wiki80</sub>.

For the convenience of calculation, we use matrices to describe all the vertices and edges (also the entities and relations) features in the document metaknowledge  $M_i$ , so the isolated vertices features (ignoring its neighbors) are:

<sup>1</sup> [github.com/scottyih/STAGG](https://github.com/scottyih/STAGG)

$$\mathbf{V}_i = \begin{bmatrix} v_{ic1} & v_{iu1} & t_i \\ v_{ic2} & v_{iu2} & t_i \\ \vdots & \vdots & \vdots \\ v_{icn} & v_{iun} & t_i \end{bmatrix}, \quad (8)$$

and the type features of vertices are:

$$\mathbf{T}_i = [v_{it1} \quad v_{it2} \quad \cdots \quad v_{itn}]^\top. \quad (9)$$

Meanwhile, the relation type features are denoted as:

$$\mathbf{r}_i = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & & \vdots \\ r_{n1} & r_{n2} & \cdots & r_{nn} \end{bmatrix}, \quad (10)$$

where  $r_{xy} = \#RelationType$ ,  $x, y \in [1, n]$ ; for vertex (entity)  $x$ , if  $y$  is one of the  $k$  nearest one-hop neighbor, then  $\#RelationType$  indicates the type number in  $|\mathcal{R}|$  of the relation between vertices  $x$  and  $y$ , otherwise  $\#RelationType = 0$ .

Therefore, for all the vertices  $V_i = \{V_{Hi} \cup V_{Si}\}$  in  $M_i$ , their features are:

$$\mathbf{H}_i = [\mathbf{h}_1 \quad \mathbf{h}_2 \quad \cdots \quad \mathbf{h}_n]^\top = \text{concat}(f_s(\mathbf{V}_i), f_t(\mathbf{T}_i), f_r(\mathbf{r}_i)), \quad (11)$$

where  $\text{concat}(\cdot)$  indicates concatenation by column, and  $f_r$  indicates a linear transformation from  $\mathbb{R}^n$  to  $\mathbb{R}^{D/2}$  in Eq.8.

When considering the semantic information in relations, we define the Semantic Relation Matrix of  $M_i$  as:

$$\mathbf{R}_i = LM \left( \begin{bmatrix} \text{text}(r_{11}) \\ \text{text}(r_{12}) \\ \vdots \\ \text{text}(r_{nn}) \end{bmatrix} \right)_{n^2 \times D}. \quad (12)$$

Using  $\mathbf{A}_i$  to indicate the adjacency matrix of  $M_i$ , then:

$$(\mathbf{A}_i)_{n \times n}, (\mathbf{H}_i)_{n \times 4D}, (\mathbf{R}_i)_{n^2 \times D} = \text{GENC}(M_i), \quad (13)$$

where  $\text{GENC}(\cdot)$  denotes GE4MK,  $\mathbf{R}_i$  only includes semantic relation, not hierarchical relations. Then we use GE4MK to encodes  $\mathcal{G}_q$  from text-described data to matrices:

$$(\mathbf{A}_q)_{n \times n}, (\mathbf{H}_q)_{n \times 4D}, (\mathbf{R}_q)_{n^2 \times D} = \text{GENC}(\mathcal{G}_q), \quad (14)$$

#### 2.4. Graph Reasoning: MEGr-Net

Inspired by R-GCN[rgcn] and GAT[gat], according to the complex semantic and hierarchical relations, this work proposes a graph-attention-based model MEG-Net (**Metaknowledge Enhanced Graph reasoning Network**) in order to perform reasoning on the question subgraph  $\mathcal{G}_q$  (Figure 4).

Relational Graph Attention Layer (R-GAL) is the basic part of MEGr-Net, the output is the vertex state features under  $k$ -heads attention influence. We denote total number of vertices as  $N = |\mathcal{V}_q|$ , the vertex features input to R-GAL as  $\mathbf{H} = \{\mathbf{h}_1, \mathbf{h}_2, \cdots, \mathbf{h}_N\}$ ,  $\mathbf{h}_i \in \mathbb{R}^F$  ( $F$  is the dimension of vertex state space), and the relations as  $\mathbf{R} = [\vec{r}_{11}, \vec{r}_{12}, \cdots, \vec{r}_{1N}, \cdots, \vec{r}_{N1}, \cdots, \vec{r}_{NN}]_{N^2 \times F}$ ,  $\vec{r}_{ij} \in \mathbb{R}^{F_r}$  ( $F_r$  is the dimension of edge state space).

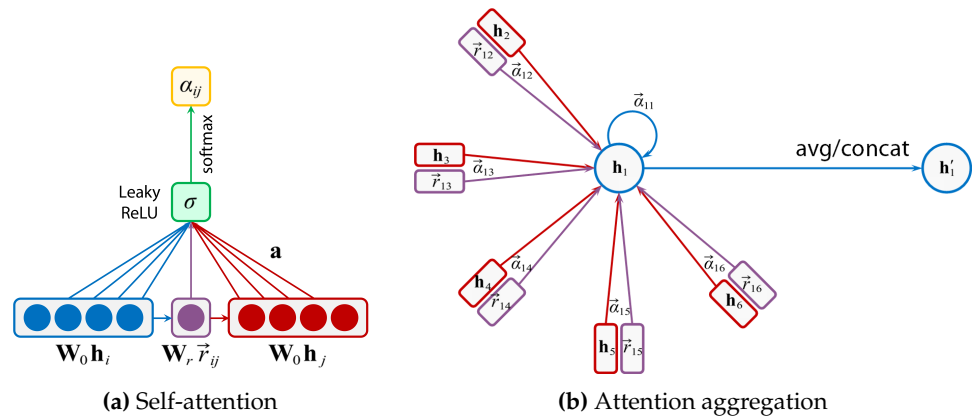

Figure 4. The attention mechanism of MEGr-Net

We firstly consider the interaction between vertex  $v_i$  and its  $k$ -neighbors (attention heads). The semantic relation matrix  $\mathbf{R}_q$  from  $GENC(\mathcal{G}_q)$  is transformed into relation features matrix  $\mathbf{R}_k$ :

$$\mathbf{R}_k = del \left( \begin{bmatrix} \vec{r}_{11} & \vec{r}_{12} & \cdots & \vec{r}_{1N} \\ \vec{r}_{21} & \vec{r}_{22} & \cdots & \vec{r}_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ \vec{r}_{N1} & \vec{r}_{N2} & \cdots & \vec{r}_{NN} \end{bmatrix}_{N \times NF_r} \right) = \begin{bmatrix} \vec{r}_{1n_1^1} & \cdots & \vec{r}_{1n_1^k} \\ \vdots & \ddots & \vdots \\ \vec{r}_{Nn_N^1} & \cdots & \vec{r}_{Nn_N^k} \end{bmatrix} = (\vec{r}_{i\mathcal{K}_i})_{N \times kF_r}, \quad (15)$$

where  $del(\cdot)$  indicates deleting all the empty relations,  $\mathcal{K}_i = \{n_1^1, \dots, n_1^k\}$  indicate the  $k$ -neighbors of  $v_i$ .

The attention mechanism is denoted as  $att : \mathbb{R}^{F'} \times \mathbb{R}^{F'} \rightarrow \mathbb{R}$ , then we calculate the attention coefficients:

$$\hat{\alpha}_{ij} = att(\mathbf{W}_0 \mathbf{h}_i, \mathbf{W}_0 \mathbf{h}_j) + att(\mathbf{W}_r \vec{r}_{i\mathcal{K}_i}, \mathbf{W}_r \vec{r}_{j\mathcal{K}_j}), \quad (16)$$

where  $\mathbf{W}_0 \in \mathbb{R}^{F \times F'}$  is the *vertex weight matrix*, and  $\mathbf{W}_r \in \mathbb{R}^{F_r \times F'}$  is the *edge weight matrix*. These two matrices realize the parallel computation of linear transformation on each vertex.  $\hat{\alpha}_{ij}$  indicates the interaction of the relation between vertex  $v_i$  and its neighbor  $v_j$ , as well as itself (self-attention). In MEGr-Net, the masked-attention mechanism is used to distribute the attention interaction to the  $k$ -neighbors  $Ne(i)$  of  $v_i$ , so the masked-attention coefficient is:

$$\alpha_{ij} = \text{softmax}(\hat{\alpha}_{ij}) = \frac{\exp(\hat{\alpha}_{ij})}{\sum_{k \in Ne(i)} \exp(\hat{\alpha}_{ik})}. \quad (17)$$

The MEGr-Net sets the attention mechanism as a single-layer feed forward network (FFN) with parameters  $\mathbf{a} \in \mathbb{R}^{2F'}$  and LeakyReLU activate function, then:

$$\begin{aligned} \alpha_{ij} &= \frac{\exp(\text{FFN}(\hat{\alpha}_{ij}))}{\sum_{k \in Ne(i)} \exp(\text{FFN}(\hat{\alpha}_{ik}))} \\ &= \frac{\exp(\text{LeakyReLU}(\mathbf{a}^\top [\mathbf{W}_0 \mathbf{h}_i, \mathbf{W}_0 \mathbf{h}_j] + \mathbf{a}^\top [\mathbf{W}_r \vec{r}_{i\mathcal{K}_i}, \mathbf{W}_r \vec{r}_{j\mathcal{K}_j}]))}{\sum_{k \in Ne(i)} \exp(\text{LeakyReLU}(\mathbf{a}^\top [\mathbf{W}_0 \mathbf{h}_i, \mathbf{W}_0 \mathbf{h}_k] + \mathbf{a}^\top [\mathbf{W}_r \vec{r}_{i\mathcal{K}_i}, \mathbf{W}_r \vec{r}_{k\mathcal{K}_k}]))}. \end{aligned} \quad (18)$$

Next, updating the vertex features of  $v_i$ :

$$\mathbf{h}'_i = \sigma \left( \sum_{j \in Ne\{i\}} \alpha_{ij} (\mathbf{W}_0 \mathbf{h}_j + \mathbf{W}_r \vec{r}_{ij}) \right), \quad (19)$$

where  $\sigma(\cdot)$  is a non-linear function, we use the ELU in MEGr-Net.

When considering the multi-heads attention, we have:

$$\mathbf{h}'_i = \big\|_{k=1}^K \sigma \left( \sum_{j \in Ne\{i\}} \alpha_{ij}^k (\mathbf{W}_0^k \mathbf{h}_j + \mathbf{W}_r^k \vec{r}_{ij}) \right), \quad (20)$$

where  $\big\|_{k=1}^K$  indicates the concatenation of  $k$  vertex features of  $v_i$  under its  $k$ -neighbors attention interaction.

In the last R-GAL, we calculate the average features instead of concatenating, and use logistic sigmoid to normalize the output features into  $[0, 1]$  as the probability  $p_i$  that indicates vertex  $v_i$  is the answer entity:

$$\mathbf{h}'_i = \sigma \left( \frac{1}{K} \sum_{k=1}^K \sum_{j \in Ne\{i\}} \alpha_{ij}^k (\mathbf{W}_0^k \mathbf{h}_j + \mathbf{W}_r^k \vec{r}_{ij}) \right), \quad (21)$$

$$p_i = \text{sigmoid}(\mathbf{h}'_i). \quad (22)$$

For the efficiency of computation, we use matrices in MEGr-Net to describe the whole progress: First, the vertex features matrix  $\mathbf{H}$  of question subgraph  $\mathcal{G}_q$  is multiplied by the vertex weight matrix  $\mathbf{W}_0$  for state space transformation. Then an all-combination is used to concatenate  $\mathbf{W}_0 \mathbf{h}_i$  and  $\mathbf{W}_0 \mathbf{h}_j$  in Eq.16:

$$\text{allc}(\mathbf{W}_0 \mathbf{H}) = (w_0 h_i)_{N^2 \times F} = \begin{bmatrix} w_0 h_1 & \cdots & w_0 h_1 & \cdots & w_0 h_N & \cdots & w_0 h_N \\ w_0 h_1 & \cdots & w_0 h_N & \cdots & w_0 h_1 & \cdots & w_0 h_N \end{bmatrix}^\top. \quad (23)$$

We do the same operation to  $\mathbf{R}_k$ :

$$\begin{aligned} \text{allc}(\mathbf{W}_r \mathbf{R}_k) &= (w_r \vec{r}_{i\mathcal{K}_i})_{N^2 \times F} \\ &= \begin{bmatrix} w_r \vec{r}_{1\mathcal{K}_1} & \cdots & w_r \vec{r}_{1\mathcal{K}_1} & \cdots & w_r \vec{r}_{N\mathcal{K}_1} & \cdots & w_r \vec{r}_{N\mathcal{K}_N} \\ w_r \vec{r}_{1\mathcal{K}_1} & \cdots & w_r \vec{r}_{1\mathcal{K}_N} & \cdots & w_r \vec{r}_{1\mathcal{K}_1} & \cdots & w_r \vec{r}_{N\mathcal{K}_N} \end{bmatrix}^\top. \end{aligned} \quad (24)$$

Then the attention coefficient vector:

$$\mathbf{ff} = \text{soft max} \left( \text{FFN} \left( \mathbf{a}^\top (\text{allc}(\mathbf{W}_0 \mathbf{H}) + \text{allc}(\mathbf{W}_r \mathbf{R}_k)) \right) \right). \quad (25)$$

Updating the vertices' state:

$$\mathbf{H}' = \big\|_{k=1}^K \sigma \left( \mathbf{ff}^k (\mathbf{W}_0^k \mathbf{H} + \mathbf{W}_r^k \mathbf{R}_k) \right), \quad (26)$$

and aggregating:

$$\mathbf{H}' = \sigma \left( \frac{1}{K} \sum_{k=1}^K \sum_{j \in Ne\{i\}} \mathbf{ff}^k (\mathbf{W}_0^k \mathbf{H} + \mathbf{W}_r^k \mathbf{R}_k) \right). \quad (27)$$

Finally, the logistic sigmoid:

$$\mathbf{p} = \text{sigmoid}(\mathbf{H}'). \quad (28)$$

### 3. Experiments

To verify the effectiveness of metaknowledge network in open domain question answering, this section carries out experiments on a subset of WebQuestionsSP, analyzes the experimental variables including: (1) triplet-based knowledge and metaknowledge, (2) various graph reasoning models, (3) several pre-trained language models.

#### 3.1. Datasets and Set-ups

This work uses the open domain natural language question answering dataset WebQuestionsSP [31] for experimental analysis, which includes 4737 questions in natural language. At present, there is no well-established large-scale metaknowledge base and metaknowledge network, so we have to build it from scratch by the approach designed in Section 2.1 and 2.2. For the fact that the entities and relations extracted by open source NLP models naturally have quality disadvantages, the metaknowledge network we build in this work has an innate weakness when comparing with the finely-built large-scale knowledge bases such as FreeBase and WikiData. Consequently, to make hierarchical metaknowledge and non-hierarchical triplet-based knowledge comparable on the same track, considering the data quality limitation, we adopt the general approach in the construction of knowledge graph, that is, deleting all hierarchical nodes and relationships, retaining only semantic entities and relations in metaknowledge and integrating them to form a non-hierarchical triplet-based knowledge network.

Meanwhile, the process of extracting metaknowledge from Wiki documents, constructing metaknowledge network, retrieving and encoding question subgraphs takes a large amount of time and computing resources. For example, in the previous experiment, it took an average of 2h for  $4 \times 11$  GB VRAM GPU and  $2 \times 12$  Core, 24 Threads CPU to build a metaknowledge network from five Wiki documents relevant to a question and complete subgraph retrieval and its encoding. Considering the data quality and hardware, this section scaled down the dataset to 2.5% of WebQuestionsSP, that is, 250 questions in natural language. And it was divided into 150 for the training set, 50 for the cross validation set and 50 for the test set. In this section, it is referred to as  $\text{WebQuestions}_{MbQA}$ . The training parameters of MEGr-Net are shown in Table 2.

**Table 2.** The Training Parameters of MEGr-Net.

Parameters	Values
Epochs	200
Learning Rate	5e-3
Attention Heads $k$	8
Dimension of Entity Features $F'$	1000
Dimension of Relation Features $F'_r$	500
Hidden Units	1000

The semantic encoder  $LM(\cdot)$  is deployed on Server #1. The metaknowledge generation, metaknowledge network construction framework and MEGr-Net are deployed on Server #2 (see also Appendix A). A Tesla V100 GPU (with 32GB VRAM) is used for training, which takes 13.5d (325h).

This work takes the average accuracy (avg. Acc.) as the evaluation index.

#### 3.2. Experimental Control Groups

This section analyzes the impact of different experimental variables on MbQA from the following three aspects:

- **Hierarchical metaknowledge and non-hierarchical triplet-based knowledge.** This is the focus of this section, that is, what improvement hierarchical metaknowledge can make on open domain question answering compared with non-hierarchical triplet-based knowledge. In other words, whether metaknowledge and metaknowl-

edge network have superiority in open domain QA tasks. As described in §3.1, considering the extraction quality of open domain entities and relationships by open source NLP models, this section uses the same data and extraction models to build metaknowledge network (referred to as MK-Net in the experiment) and triplet knowledge base (referred to as Tri-KB) by the metaknowledge structure proposed in §2.1 and the general triplet-based knowledge structure respectively.

- **Graph reasoning model.** MEGr-Net, based on GAT, essentially achieves an improvement of graph data with complex relationships, like metaknowledge. Meanwhile, it partially adopts the relationship processing approach in R-GCN. Therefore, this section takes GAT and R-GCN as test baselines and compares them with MEGr-Net. To explain the impact of (meta)knowledge extraction quality on the results, this section introduces the results of DrQA[21] and GRAFT-Net [22] on the entire WebQuestionsSP as a reference.
- **Pre-trained language models (PLMs).** The input of MEGr-Net is the question subgraph  $\mathcal{G}_q$  encoded by GE4MK, and its semantic features mainly come from the text embedding vector encoded by the PLM  $LM(\cdot)$  in GE4MK. Therefore, different PLMs may exert different impact on the semantic feature richness of the problem subgraph. This section takes BERT<sub>BASE</sub> as the baseline, meanwhile RoBERTa [29] and ALBERT [32] as the control groups.

### 3.3. Results and Analysis

The results on control group #1 on WebQuestions<sub>MbQA</sub> are shown in Table 3. The results show that with the same data quality, the hierarchical metaknowledge achieves better results than non-hierarchical triplet knowledge in open domain question answering(+16.9% Tri-KB).

**Table 3.** Results on Control Group #1.

(Meta) knowledge Network	IH-Acc <sup>#</sup> .
Tri-KB	0.483
<b>MK-Net</b>	<b>0.652</b>

<sup>#</sup> The WebQuestions<sub>MbQA</sub> dataset which we use in the experiment is part of the whole WebquestionsSP, so we use average In-House Accuracy (IH-Acc.) for avg. Acc.

The results on control group #2 are shown in Table 4. For GAT, the relationship matrix  $\mathbf{R}_k$  in MEGr-Net and the relationship weight matrix  $\mathbf{W}_r$  in R-GAL are removed in this section. Modifications have been made to R-GCN for the tasks in this section.

**Table 4.** Results on Control Group #2.

Graph Reasoning Models		Acc.
Baselines	GAT (MK-Net)	0.608 (IH <sup>†</sup> )
	R-GCN <sup>#</sup> (MK-Net)	0.601 (IH)
	MEGr-Net (MK-Net)	0.652 (IH)
	DrQA (doc only)	0.215
	GRAFT-Net (KB+doc)	0.687

<sup>#</sup>Model from [github.com/kkteru/r-gcn](https://github.com/kkteru/r-gcn).

<sup>\*</sup>The data is cited from [22], respectfully.

<sup>†</sup>IH indicates that the experiments are based on the dataset WebQuestions<sub>MbQA</sub>, and if not annotated, that indicates that the experiments are based on the dataset WebQuestionsSP.

As can be seen from the results, MEGr-Net achieves better performance than the baselines in the reasoning of hierarchical graph data with complex semantic relationships, such as metaknowledge network (+4.4%GAT, +5.1%R-GCN). Meanwhile, compared with GRAFT-Net, which uses the complete FreeBase as the knowledge base and integrates the document (doc) and KB features, MEGr-Net still lags behind, indicating that it still needs to be improved in MbQA, especially in the integration with MRC method (see also Section 4).

The results on control group #3 are shown in Table 5 (see Appendix B for the source of the pre-training parameter file of the pre-training language model). From the results, the PLMs (ALBERT<sub>XXLARGE</sub>, RoBERTa<sub>LARGE</sub>) with large-scale parameters perform better, indicating that the larger the PLMs used by the graph encoder, the finer the fine tuning and the richer the semantic features of the question subgraph, the better performance will be achieved in MbQA.

**Table 5.** Results on Control Group #3.

MEGr-Net	PLMs	IH-Acc.
Baseline	+BERT <sub>BASE</sub>	0.652
	+ALBERT <sub>BASE</sub>	0.646
	+BERT <sub>LARGE</sub>	0.670
	+RoBERTa <sub>LARGE</sub>	0.692
	+ALBERT <sub>XXLARGE</sub>	<b>0.708</b>

As shown in Figure 5, the combination of MEGr-Net and ALBERT<sub>XXLARGE</sub> achieved the best results (+5.6% MEGr-Net+BERT<sub>BASE</sub>) and gained better performance than GRAFT-Net using LSTM [lstm] as text encoder, which proves that PLMs based on Transformers [26] is better than LSTM in MbQA.

**Figure 5.** Results of Graph Reasoning Models and PLMs in MbQA.

Generally, the metaknowledge network with document directory hierarchy can significantly improve the existing methods in KBQA, which is basically consistent with the view that titles play a positive role in question answering in [22]. Meanwhile, finer PLMs can improve the semantic feature representations of question subgraphs and achieve better results in question answering. This is also consistent with the view and experimental results in [33].

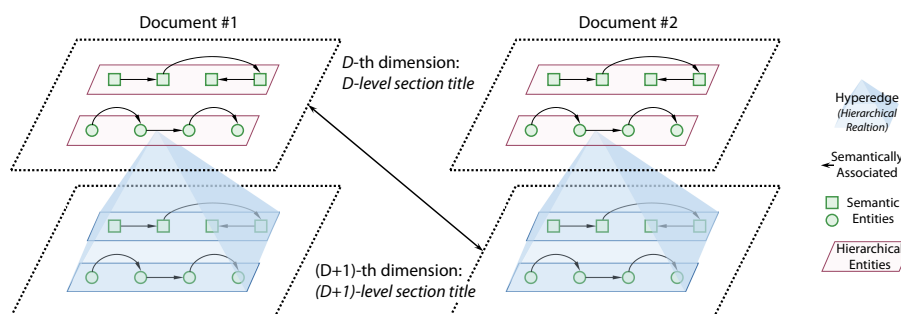

#### 4. Discussion

From the overall results of this work, metaknowledge basically solves the problems of triplet-based knowledge with weak structural logic, and provides a new idea for the theoretical and practical research of knowledge engineering. Meanwhile, it must also be noted that, as a relatively new research field, there are still some urgent problems need to be solved in the future work.

- **Metaknowledge and Metaknowledge Network Modeling**

Metaknowledge and metaknowledge network modeled by the single dimension network in this work (Section 3.2 & 3.3) is a compromising strategy to reduce the complexity of the model under the current realistic conditions of mainstream GNN models. In fact, according to the our concept, the metaknowledge network should be a multi-dimensional hyper-graph with hierarchical structure (Figure 6). The metaknowledge network expressed by that type of graph model includes two dimensions: hierarchical dimension and semantic dimension. The hierarchical dimension is in the outer layer, which includes all hierarchical nodes and relationships; The semantic dimension is in the inner layer, which includes all semantic nodes and relationships subordinate to

the hierarchical nodes. Ref.[34] proposes an embedding framework MINES for multi-dimensional networks with hierarchical structure, which uses hierarchical structure for multi-dimensional network embedding; Ref.[33] proposes an open domain question answering method based on hyper-edge fusion. These documents show the feasibility of graph reasoning on the metaknowledge network expressed by hierarchical multi-dimensional hyper-graph. This metaknowledge modeling method needs to be further studied and explored.

**Figure 6.** Metaknowledge that modeled by multi-dimensional hyper-graph with hierarchical structure.

- **MbQA and Graph Reasoning**

Limited by the extraction effect of open-source NLP models, MbQA has insufficient advantages over KBQA. At least under the existing conditions, there is still a huge gap between the metaknowledge network and mutual large-scale knowledge bases such as freebase from the perspective of data quality. Therefore, MbQA may be more suitable for in-domain QA tasks (such as question answering on laws and regulations). The fine-tuned NLP models will significantly improve the extraction quality of metaknowledge semantic elements. At the same time, the structural logic of metaknowledge network makes it have the ability to deal with complex relationships. Therefore, the role of metaknowledge network in multi-hop QA tasks is also a direction worthy of research. In terms of graph reasoning models for question answering tasks, MEGr-net relies on the hierarchical features contained in metaknowledge to supplement the short board relying only on semantic features (KBQA). On this basis, documents [22] and pre-trained language models [35] can continue to be integrated into graph reasoning to select the best from the best and enhance the effect of MbQA.

## 5. Conclusions

Facing the problems in current open domain QA tasks caused by the loose knowledge association and weak structural logic of triplet-based knowledge, this work make pivotal innovations on metaknowledge enhance question answering: (1) **Metaknowledge extraction and metaknowledge network construction**, where we present the approach of generating metaknowledge and building metaknowledge network from Wiki documents automatically. (2) **Metaknowledge and metaknowledge network modeling**, where we generally consider several different kinds of features from reasoning performance related aspects including semantic features such as textual content, entity type, relations, along with hierarchical features. (3) **MEGr-Net**, which is proposed for question answering, which aggregates both relational and neighboring interactions comparing with R-GCN and GAT. Experiments have proved the improvement of metaknowledge over main-stream triplet-based knowledge. We have found that the graph reasoning models and pre-trained language models also have influences on the metaknowledge enhanced question answering approaches.

Server #1: Providing BERT Embedding Service		
Hard-ware Env.	CPU	2Intel Xeon E5-2678 v3 (48) @ 3.300GHz
