Abstract: The Potassium Ribosate, which has been shown to have an enhancer effect in limiting replication and viability in cancer cells, also appears to show promise in alterating viral replication. To determine its activity against SARS-CoV-2, an inhibition assay was performed using 26 strains obtained from clinical samples from patients isolated on the Vero E6 cell line. For this, the strains were serially diluted and treated with 125mM Potassium Ribosate. The Potassium Ribosate was administered at a single concentration (125mM stock) in two ways: 24 hours before infection and in the culture medium after removal of the infectious inoculum. The culture medium was changed 3 days after inoculation. Seven days after inoculation, a visual reading of the cytopathic effect (ECP) and RT-qRCP were performed to calculate the viral load. Reduction of 3log (9Ct) between with or without Ribosate was considerate a very good response. Of the 26 evaluable strains, a reduction in viral replication was observed in 13 (50%) and 16 (61.5%) of the pre-treatment and treatment study (p=0.29). This response was good or very good in 10 (38.4%) and 11 (42.3%) (p=0.4), respectively. Potassium Ribosate administration reduced the viral load of SARS-CoV-2 cultures in Vero E6 cells in more than half of the cases, both at infection and pre-infection administration.

Keywords: SARS-CoV-2; potassium; ribose; immune response

One of the current challenges in SARS-CoV-2 infection is finding reagents/drugs/products that control viral replication directly (antivirals) or indirectly (immunomodulators).

Numerous reviews of SARS-CoV-2 have been conducted in the scientific literature. [1a,b,c] All this knowledge is of relevance to the identification and understanding of this disease in the face of the different treatments that may continue to emerge. This background evidence shows that the immune response and possible early evasion play a crucial role in decreasing the viral load or infectious dose that governs disease severity and transmission. [2a,b,c]

Potassium Ribosate (RK), is a compound that has been studied for several years by the Biochemical Research A.E.I.E., in collaboration with the Valsé Pantellini Foundation. These structures have been developing research projects based on Potassium salts, in particular Potassium Ascorbate and Potassium Ribosate, for several years on the basis of the studies of the Italian biochemist Gianfrancesco Valsé Pantellini in the second half of the last century and published between 1970 and 1999. [3–6]. The main objective of the above-mentioned projects was to assess the impact of these molecules to try to both prevent and combat degenerative pathologies, in particular oncological ones. Over the years, collaborations have been launched that have produced encouraging results both "in

*vitro*" [7–15] and "*in vivo*", [16–19] developing a rational rationale for the use of these molecules. [18] We know that potassium is a very important metabolic regulator, [20–22] but is particular characteristic of stabilising telomeres through the so-called G-quadruplexes seems less well known.[11–14,23]

It is this last feature that has allowed to focus attention on viral issues, with special attention to SARS-CoV-2, assuming that Potassium may interfere with viral replication thanks to its action of maintenance and stabilisation of the genetic structure, inhibiting or limiting retrotranscription.[24a] The mechanism underlying this action is the physical process of resonance, within the biophysical paradigm of living systems.[24b] In this way, Potassium Ribosate could be used as a therapeutic method. It should be noted that preliminary tests in mice treated with RK showed no acute toxicity of the compound (Acute Toxicity Study, according to GLP regulations). [25]

Therefore, a study has been developed to assess the influence of RK on SARS-CoV-2. The Virology section of the Microbiology laboratory Services of the Hospital Universitario Central de Asturias (HUCA) and the Foundation for Biosanitary Research of Asturias in conjunction with Biochemical Research A.E.I.E. developed an in vitro viral growth inhibition assay to monitor whether the active ingredient RK increased the resistance or defence capacity of the cell against SARS-CoV-2 infection.

#### **Material and Methods**

Material

All assays were performed in the biosafety laboratory of the Virology Section of the HUCA under appropriate safety conditions.

In order to carry out the different inhibition assays and to quantify the effectiveness of aqueous Potassium Ribosate (Biochemical Research A.E.I.E., Spain) against the SARS-CoV-2 viral pathogen, a total of 29 strains were used, which were processed at three different times in the following way: 6 different strains in assay-1, 8 different strains in assay-2 and 15 strains, also different, in assay-3. These strains belonged to variant B.1.1.1.1.7 ( $\alpha$ ), all these strains were isolated from clinical samples in established Vero-E6 cell line, according to standardised protocols and stored in the viral section's biobank. Classification of the variants corresponding to each of the strains was performed either by allelic discrimination techniques or by sequencing, according to the protocol of the Section.

# Methods

For the inhibition assays, the viral titre of each strain was determined before or at the same time as the assay, depending on the needs of the moment (as determined later).

Once the titre of each strain was determined, the inhibition study was carried out according to classical methods adapted in the laboratory. [26–29]

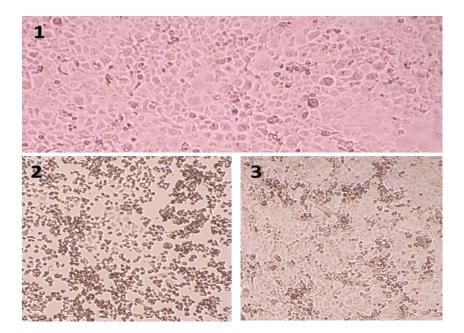

### a) Strain titration

Strains of all SARS-CoV-2 viruses were titrated for 50% CI according to inoculation assays in 96-well plates with confluent cell substrate (Vero-E6 cells). For this, starting from a viral culture, decreasing dilutions of the virus were made in base 10 and  $200\mu l$  of the inoculum was inoculated into the wells of the plate. They were then incubated at  $37^{\circ}$ C for 1 hour in a 5% CO2 atmosphere. The inoculum was then removed and incubated for up to 7 days under the conditions described above.

Viral growth was determined by DBS, Neutral Red and/or PCR.

#### (a.1) Cytopathic Effect (CPE)

The Karber Method was performed by visualizing the cytopathic effect produced by the infection and calculating the IC 50% (Figure 1).

**Figure 1.** Images of cultures: (1) Uninfected Vero E6 cells; (2) CPE of titre -2 of a strain at 7 days; (3) CPE of titre -5 at 7 days.

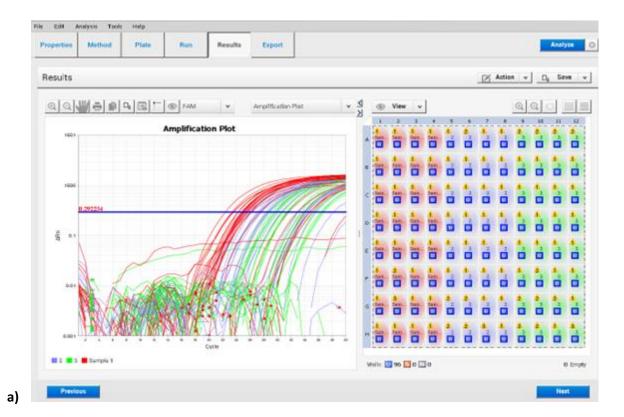

#### (a.2) Vital Dye (Neutral Red)

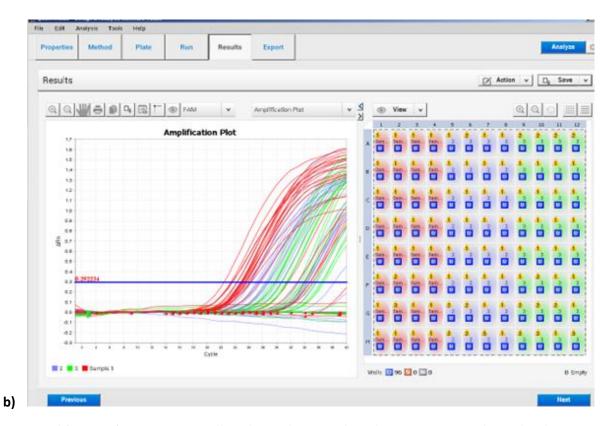

To assess viral infection more accurately, the Neutral Red vital dye uptake method was sometimes applied: after 7 days of infection in the 96-well plate,  $50\mu$ l of a buffered Neutral Red solution was added to each well. The plates were incubated for 45 minutes at 37°C and in a 5% CO2 atmosphere. Subsequently, the medium was removed, and the wells were washed twice with PBS. Finally,  $150\mu$ l of ethanol phosphate buffer was added to elute the vital dye incorporated by the viable cells. The absorbance was read at 550nm (reference value of 620nm) on a PR 4100 spectrophotometer.

# (a.3) Genomic Detection and Quantification: Real-Time RT-PCR of SARS-Cov2

From each well,  $50\mu l$  of supernatant was collected for subsequent viral quantification by genomic amplification (PCR, Figure 2). Viral replication in each of the cell culture dilutions was determined by averaging the viral load of all wells, by qPCR technique routinely used in the HUCA Virology Laboratory for virus diagnosis. [30,31] Briefly, once the viral genome was extracted with the Magnapure LC96 system (Roche Diagnostic, S.L., Switzerland), 5  $\mu l$  was mixed with 10  $\mu l$  of a reaction containing specific primers and MGB probes against the polymerase fragment and the N gene and with Fast-stepone 4x reagent (ThermoFisher, S.A. USA).

The results obtained were expressed as a function of the Ct (PCR cycles) observed (the higher the Ct the lower the viral load). A Ct of 40 is assumed to mean no viral growth.

**Figure 2.** Amplification of SARS-Cov2 in wells without Ribosate (red), with pre-treatment (violet) and without pre-treatment (green) in logarithmic (a) and linear (b) scale.

# (b) Inhibition assay

In the trials carried out with different strains, two types of Potassium Ribosate administrations were performed: 24 hours prior to virus inoculation, which is referred pre-treatment; or immediately after pathogen inoculation, which is referred treatment.

At all times, the concentration at which Potassium Ribosate was administered was 125mM (Stock concentration as stated by Biochemical Research A.E.I.E., derived from in vitro assays). [14–22,32]

To infect the cells, the medium was removed and 200 µl of each of the serial dilutions were added and incubated at 37°C for 1 hour in a 5% CO2 atmosphere. Subsequently, the inoculum was removed, and fresh maintenance medium was administered without and with RK. Three days after infection, the medium was renewed, and each culture was maintained under the same conditions as the original ones. In all cases, viral replication was measured at 7 days post-inoculation. These were performed by visualization of the cytopathic effect and by PCR quantification (molecular readout).

In the latter assay, analysis by Neutral Red staining was added in some cases. In order to assess the results obtained and quantify the degree of impact of Potassium Ribosate on viral replication of the different strains used in the assays, the following scale of criteria was developed:

# (b.1) Biological Readout Response (DBS/Neutral Red):

- DBS: difference of more than 2 log between the titre with and without reagent.
- Neutral Red: less than 50% growth in the reading title.

#### (b.2) Molecular Readout Endpoints (RT-PCR):

- Less than 3 cycles difference: No response (NR)
- Between 3 and 6 cycles (or between 1 and 2 log): Response (R)
- Between 6 and 9 cycles (or between 2 and 3 log): Good Response (B)
- More than 9 cycles (or more than 3 log): Very Good Response (MB)

The final interpretation of the results was carried out according to the data obtained with the RT-PCR method as it better discriminates the difference in growth. The CPE and Neutral Red reading data (when used) were used to assess the evolution of the assay and to confirm the more accurate data from the RT-PCR method.

This study was conducted in accordance with the Declaration of Helsinki of 1964 and its subsequent amendments (as revised in 2013). Due to the study design, local Ethical Committee approval was not required. No personal data were handled during the study.

#### Experimental Results.

Description and characteristics of each assay

As mentioned above (in the methods section), three trials were carried out at different time periods.

In assay-1, the pure control results and the cells from the plate detached from the plate of 6 strains were assessed. In assay-2, 8 strains were assessed and in assay-3, 15 strains were assessed. All data from these three trials are shown in Table 1.

Of the 29 strains tested, evaluable results were obtained in 26. Overall, a response was observed in 13 (50%) pre-treated and 16 (61.5%) treated strains at inoculation (p=0.29). This response was good or very good in 10 (38.4%) of the pretreated and 11 (42.3%) of the treated strains (p=0.4).

# Discussion

SARS-CoV-2 generates a wide range of clinical manifestations ranging from infection with mild symptoms to severe disease. Studies show that the total viral load to which the individual is exposed is relevant. Damm et al. have found that there is a dose-dependent relationship between viral load and disease severity, so it is important to assess the change in viral load over time, defined as viral

kinetics. [33] The systematic review by Billah et al. shows that assessing this parameter could provide insight into the possibility of an increase in CoV infections. [34]

The basis for this study, lies in the immune response and early evasion of the virus. In this respect, many studies have been carried out with different products tested with varying degrees of success. [35–40]

It should be emphasized that the compound under test, Potassium Ribosate, is not an antiviral, so it is necessary to interpret its ability, highlighted in some strains, to strongly reduce viral replication with a significant reduction of viral load. As mentioned in the introductory part, the working hypothesis formulated by Biochemical Research A.E.I.E., together with the Valsé Pantellini Foundation, is that the Potassium present in the compound acts on the G-quadruplexes (G4) not only of human DNA, for their formation and stabilisation, [45] but also and above all on the mRNA of the SARS-CoV-2 coronavirus.[46] Only the stabilisation of these structures by a compound or, more specifically, an element, such as the cation K<sup>+</sup>, which interacts with G4, can reduce viral RNA replication and inhibit protein translation.[47]

In this work, a reagent has been tested which, on the one hand, aims to improve cellular defence against alpha variants of SARS-Cov2 and, on the other hand, could act on the virus itself (although its mechanism of action is not known). Potassium Ribosate was able to alter viral replication in more than 60% of the strains. And this response was good or very good in 40% of these strains, suggesting that it is a good drug to alter viral replication and fight infection. [41–44a,b]

These results are in line with other recently tested reagents, which, although they do not reach the 80% efficiency values of direct antivirals, do present values above 60%, similar to those presented in this work. [48] To evaluate its activity, three trials were carried out, in all of which pretreatment and treatment were evaluated (as detailed in Material and Methods), in different periods due to the workload involved. And we worked with the alpha variant, which was the one available in the laboratory at the time. During the evaluation, the SARS-Cov2 typology was not modified so as not to introduce new variables that could alter the final result. The results obtained at the end of each trial for both Pretreatment and Treatment revealed viral load reductions of 50% and 61.5%; this response was Good or Very Good in 10 (38.4%) and 11 (42.3%) of the strains, respectively. In all cases that resulted in a "Very Good Response" the cytopathic effect was negative, showing the weakness of the virus to continue to affect these cultures.

In summary, administration of Potassium Ribosate reduces the viral load and cytopathic effect of SARS-CoV-2 cultured in Vero E6 cells in more than half of the cases and can be considered as a possible therapeutic/immunomodulatory method aiming to minimize viral replication in the early undetectable stages and its infectious capacity. Of course, the subject is complex, but the working hypothesis formulated may shed new light on the inhibition of viral replication using a simple and physiological molecule such as Potassium Ribosate and may open the door to further studies to better understand the mechanisms involved.
