**Abstract:** Stem cell-derived liver cells, organoids, and lab-grown liver tissue are promising regenerative therapies for liver disease. However, current culture conditions are sub-optimal, producing end-target cells and tissue phenotypes that are immature when compared to primary liver cells and tissue. Biopolymers used in culture substrates and scaffolds for tissue engineering significantly impact the quality of end-target cells and tissue, influencing the efficacy of regenerative treatments. In addition, the biochemical properties of some biopolymers may even preclude the translation of downstream products into clinical practice. Therefore, this systematic review aims to evaluate the recent advances in biopolymers within liver tissue engineering, providing an overview of the current usage in the field and highlighting novel substrates that have the potential to be easily translated into clinical therapy.

---

## 1. Introduction

The incidence of liver disease is increasing globally [1]. It is the second most common cause of premature deaths in the Europe, America, and Africa, and the third most in South-East Asia [2]. Over time, chronic liver disease can lead to liver cirrhosis and liver failure. At present, the only cure for end-stage liver failure is liver transplantation, however, the patient demand far exceeds donor supply. In the United Kingdom alone, patients wait an average of 3 to 4 months for a liver transplant for chronic liver failure [3]. Unfortunately, approximately 10% of these patients die on the waiting list due to complications of their liver disease, and even a greater number are turned down for transplantation [4,5]. Therefore, novel therapies for the treatment of liver failure are urgently needed.

Bioengineering liver tissue from human stem cells and organoids offers excellent potential as an alternative to conventional liver transplantation. Vast quantities of cells and/or tissue could be generated *in vitro*, relieving the strain on the limited donor pool. In addition, hepatocytes, cholangiocytes, or liver organoids derived from patient-specific stem cells enable the autologous transplantation of end-target cells or tissue, thereby negating the need for long-term immune suppression and its associated side effects, which are often encountered with non-autologous liver transplantation. For example, Japanese researchers have successfully transplanted hepatocytes derived from human embryonic stem cells into an infant with urea cycle disorder, temporarily reversing the disease so that a liver transplant could be performed safely five months later [6]. Apart from cell therapy or tissue transplantation, regenerative approaches can also be used for disease modelling and predicting response to novel drug therapies more accurately [7–9]. It is noteworthy that approximately half of the drugs that have caused drug-induced liver injury in humans did not

have any significant liver-toxic effects in animal testing [10]. In contrast, stem cell-derived liver models, such as bioengineered liver tissue or liver-on-a-chip devices, have demonstrated good concordance between in vitro and in vivo drug toxicity, making them of strong interest to the pharmaceutical industry [11].

Despite the immense potential of stem cell-derived liver cells and tissue, it is widely recognised that current culture conditions are sub-optimal and yield immature end-target cells compared to primary cells [12,13]. A key factor attributed to this shortcoming is the lack of suitable biomaterials that accurately reproduce the stem cell niche during liver differentiation, both in terms of composition and dimensionality [14,15]. Three-dimensional (3D) systems and tissue-specific matrices yield better cellular phenotypes than two-dimensional (2D) culture systems and generic substrates, respectively [16–19]. However, substrates commonly used in 3D culture systems, like Matrigel, are usually xenogenic and associated with many problems. For example, growth factors such as epidermal growth factor, insulin growth factor-1 and fibroblast growth factor 2 concentrations are inconsistent between Matrigel batches [20,21]. In addition, growth-factor-reduced versions of Matrigel contain only 53% of the extracellular matrix (ECM) proteins found in Matrigel [22]. These inconsistencies cause significant biochemical and mechanical variations [23], leading to poorly reproducible in vitro results [20–24]. Furthermore, poor definability, immunogenicity [25,26] and pathogenicity [27,28] preclude its use and any downstream products from clinical therapy [29].

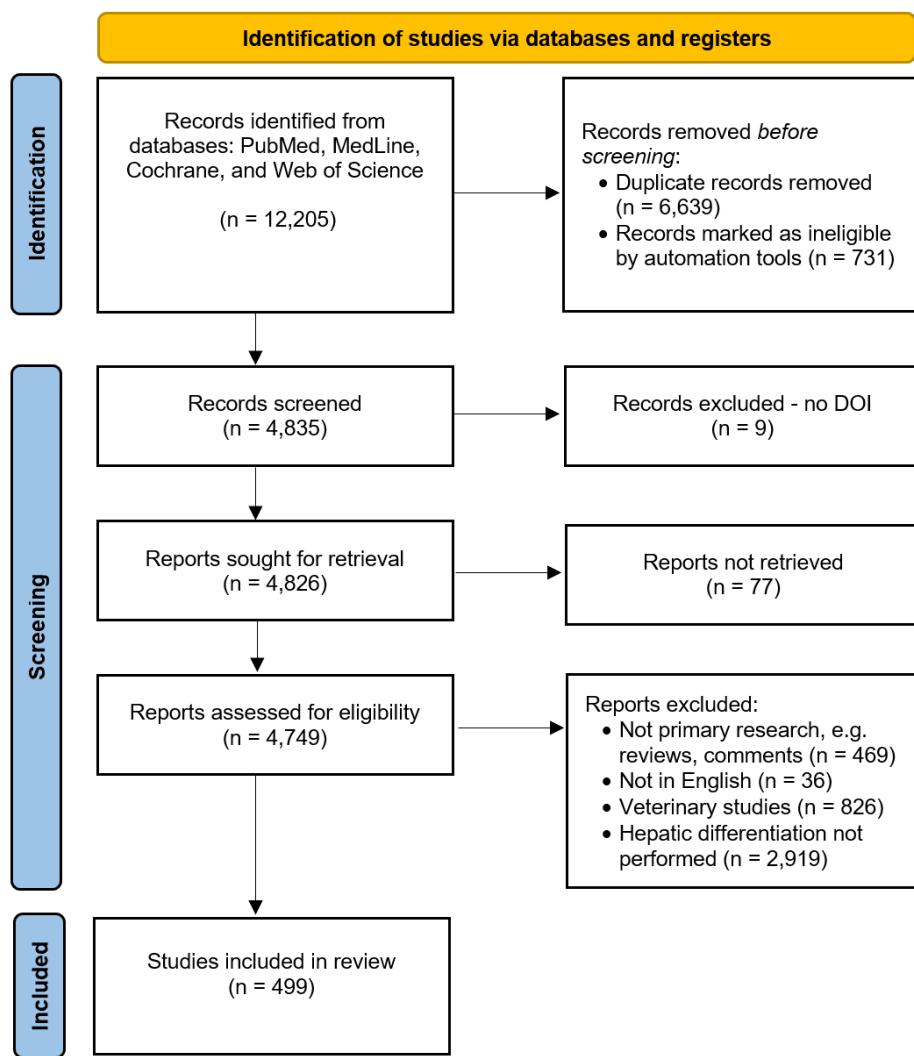

Therefore, novel and better biomaterials are urgently needed for clinical translation. The primary objective of this focused systematic review was to study the biomaterials used in liver bioengineering between 2020 and 2025, thereby understanding the direction of future practices. The secondary objective is to appraise novel biomaterials for their potential for clinical translation, focusing on definability, versatility, degradability, and biosafety. It is essential to note that different types of stem cells exhibit distinct responses to the various biopolymers within culture substrates and scaffolds based on their degree of stemness and inherent propensity to hepatic differentiation. Therefore, in the context of this review, we have classified the various types of stem cells broadly into three categories: (i) Pluripotent Stem Cells (PSCs), (ii) Liver Stem Cells (LSCs), and (iii) Non-Liver Stem Cells (NLSCs). PSCs refer to human induced pluripotent stem cells (iPSCs) and embryonic stem cells (ESCs). LSCs refer to native human hepatic or biliary human progenitor stem cells, such as LGR5+ hepatoblasts. NLSCs refer to all other human non-pluripotent and non-liver stem cells, e.g., mesenchymal stem cells (MSCs).

Herein, we present a comprehensive summary of biomaterials usage within liver bioengineering, demonstrating that xenogenic matrices are still widely used. However, we have found that chemically defined alternatives are being increasingly explored, with recombinant human proteins gaining popularity as routine practice. Finally, we discuss the advantages and disadvantages of these alternatives and provide insights on the future direction of biomaterials research.

## 2. Results and Discussion

### 2.1. Summative Results of the Systematic Searches

Four public databases were comprehensively searched for articles published between 1 April 2020 and 1 April 2025 that reported stem differentiation into liver cells, organoids, or tissue (the systematic search strategy is described in the Methods section). A total of 12,205 articles were identified. After removing duplicates and ineligible hits (n=7,370), 4,835 articles were screened for eligibility. During the screening process, 4,336 articles were excluded from further analyses, and 499 were included after meeting the inclusion criteria (see Methods section). Figure 1 illustrates the PRISMA systematic review flow diagram. Of these 499 articles, 282 used PSCs, 158 used LSCs, and 59 used NLSCs for liver bioengineering. The results of each stem cell group are reported separately below.

**Figure 1.** PRISM 2020 systematic review flow diagram, adapted from Page MJ et al., BMJ 2021 [30].

## 2.2. Biomaterials Used to Derive Liver Cells and Organoids from PSCs

Of the 282 studies that used PSCs (see Supplementary Table 1), 8 reported cholangiocyte differentiation, 197 reported hepatocyte differentiation, 86 reported liver organoid culture, 1 reported differentiation of hepatic stellate cells, and 1 reported the differentiation of liver sinusoidal endothelial cells (LSEC). 10 studies differentiated PSCs into hepatocytes AND cholangiocytes/liver organoids. 75.2% (212/282) of all these studies used Matrigel or its derivatives for maintenance or differentiation. The other types of biopolymers used are summarised in Table 1.

**Table 1.** Studies using biopolymers to bioengineer human liver from PSCs.

Biopolymer / Substrate	Maintenance	Differentiation
Matrigel	112	155
Matrigel (GFR) <sup>1</sup>	54	43
Biomimesys	-	1
Collagen-1	-	13
Cellulose	-	1

Cellartis DED coating <sup>2</sup>	-	7

Decellularised liver ECM	-	3
Feeder cells	26	3
Fibronectin	-	2
Gelatin	5	13
GelMA <sup>3</sup>	-	1
hE-cad-Fc	1	-
HepMat	-	1
Hydrox™ coating	-	1
Laminin 111	-	1
Laminin 511	20	9
Laminin 511-Silk	6	6
Laminin 521	16	18
Laminin 521-Silk (Biosilk)	1	-
PEG-coated constructs <sup>4</sup>	-	1
PEG-peptides	-	1
PLLA/PCL fibres <sup>5</sup>	-	1
PCL-Gel-HA <sup>6</sup>	-	1
Placenta ECM	1	2
PAA <sup>7</sup>	-	1
Suspension Culture	1	11
Synthemax II coating	1	1
Vitronectin	35	2

<sup>1</sup> GFR = Growth Factor Reduced, <sup>2</sup> DED = Definitive Endoderm Differentiation, <sup>3</sup> GelMA = Gelatin Methacryloyl,

<sup>4</sup> PEG = Polyethylene Glycol, <sup>5</sup> PLLA/PCL = Poly-L-lactic acid/poly ( $\epsilon$ -caprolactone), <sup>6</sup> PCL-Gel-HA = Poly  $\epsilon$ -caprolactone-gelatin-hyaluronic acid, <sup>7</sup> PAA = Polyacrylamide.

100% (8/8) of PSC studies reporting cholangiocyte culture used Matrigel or its derivatives (growth factor-reduced Matrigel). 4 of 8 studies added Collagen-1 to Matrigel derivatives for cholangiocyte differentiation. Of the PSC studies reporting hepatocyte culture, 71.1% (140/197) used Matrigel or its derivatives, 13.7% (27/197) used Laminin 511 or its derivatives (Laminin 511-silk), and 10.7% (21/197) used Laminin 521 or its derivatives (Laminin 521-silk). The remaining studies used cellulose, Cellartis Definitive Endoderm Differentiation coating, Cellartis DEF-COAT 1, PEG-peptides, gelatin, fibronectin, liver scaffolds/ECM, Hydrox™ coating (a peptide-functionalized hydrogel), Synthemax® II coating (peptides covalently bonded to an acrylate polymer backbone), placental ECM, vitronectin, PAA, PLLA/PCL, PCL-Gel-HA, and suspension culture. For three-dimensional (3D) liver and/or organoid culture, 93.4% (71/86) used Matrigel or its derivatives. The remaining studies used Biomimesys® (a hyaluronic acid-based scaffold that also contains collagen, laminin, and fibronectin), gelatin, GelMA, decellularised animal livers, Laminin 521, or PEG.

It is noteworthy that researchers have also used specific biopolymers that do not deliver chemical cues to PSCs. For example, agarose-based microfabricated hexagonal closely packed cavity arrays (mHCPCAs) have been explored as a suspension culture method [31,32]. The hypothesis is that the tightly controlled microenvironment created by mHCPCAs produces significantly less heterogeneity in organoid size, morphology, and maturation rate than standard Matrigel domes. Nonetheless, liver organoids produced by the mHCPCAs method are still noted to be immature [31,32]. Agarose is hydrophobic and lacks cell-binding motifs, which in turn promotes suspension culture, spheroid, or organoid formation [33]. The lack of mechano- and chemical cues most likely explains these results and highlights the importance of bioactive biopolymers within scaffolds.

### 2.3. Biomaterials Used to Derive Liver Cells and Organoids from LSCs

Of the 158 studies that used LSCs (see Supplementary Table 2), 3 reported cholangiocyte differentiation, 24 reported hepatocyte differentiation, 48 reported biliary organoid culture, and 89 reported liver organoid culture. 5 studies differentiated LSCs into hepatocytes and cholangiocytes/liver organoids. 76.4% (120/157) of all these studies used Matrigel or its derivatives for maintenance or differentiation. The other types of biopolymers used are summarised in Table 2.

**Table 2.** Studies using biopolymers to bioengineer human liver from LSCs.

Biopolymer / Substrate	Maintenance	Differentiation
Matrigel	90	96
Matrigel (GFR)	28	23
Collagen-1	14	11
Fibronectin	1	-
Gelatin	1	1
Gelatin-Alginate	-	1
GelMA	-	1
Hyaluronic Acid	1	1
Hydrox™	-	1
Liver ECM	-	1
Laminin 332	-	1
Laminin 511-PIC <sup>1</sup>	-	1
PIC-LEC <sup>2</sup>	-	1
PEG	-	1
PCL	-	1
Suspension Culture	3	10
No coating	21	15

<sup>1</sup> PIC = Polyisocyanopeptides, <sup>2</sup> PIC-LEC = PIC-Laminin 111-Entactin-Complex.

66.6% (2/3) of studies reporting cholangiocyte differentiation of LSCs used Matrigel or its derivatives (growth factor-reduced Matrigel); the remaining study used Collagen-1. Of the studies reporting hepatocyte differentiation from LSCs, 18.2% (4/22) used Matrigel or its derivatives. An identical proportion (4/22) used Collagen-1. 63.6% (14/22) of studies did not use any substrate, as LSC appear to be adherent cells in two-dimensional (2D) cell culture. In contrast, 93.9% (46/49) of studies used Matrigel or its derivatives for 3D biliary organoid culture; the remaining used collagen-1, hyaluronic acid or suspension culture. For 3D hepatic organoid culture, 85.4% (76/89) used Matrigel or its derivatives. The remaining studies used Hydrox™, Laminin 332, GelMA, PEG, PIC-Laminin 511, and suspension culture methods.

#### 2.4. Biomaterials Used to Derive Liver Cells and Organoids from NLSCs

Of the 59 studies that used NLSCs (Supplementary Table 3), 1 reported cholangiocyte differentiation, 52 reported hepatocyte differentiation, 1 reported liver sinusoidal endothelial cell culture, and 5 reported liver organoid culture. 3.4% (2/59) of all these studies used Matrigel or its derivatives for maintenance or differentiation. 18.6% (11/59) used Collagen-1 as a substrate. 55.9% (33/59) used no substrate. The other types of biopolymers used are summarised in Table 3. Likewise,

**Table 3.** Studies using biopolymers to bioengineer human liver from NLSCs.

Biopolymer / Substrate	Maintenance	Differentiation
Matrigel	1	-
Matrigel (GFR)	1	1
Agarose	-	1

Collagen-1	5	11
Fibronectin	3	2
Fibroin	-	1
Gelatin	3	4
Liver ECM (animal)	-	4
Lidipure coating <sup>1</sup>	-	1
Wharton's Jelly	1	1
No coating	45	33

<sup>1</sup> Phosphorylcholine-based polymer.

The only study that reported cholangiocyte differentiation from NLSCs used collagen-1. Of the studies that reported hepatocyte differentiation, 63.5% (33/52) did not use any substrate, 23.1% (12/52) used collagen-1 or gelatin, and only one used Matrigel (growth factor reduced). Fibronectin was used for the only study that differentiated NLSCs into LSECs. For 3D liver organoid culture, Collagen-1 (2/5), Agarose (1/5), Lidipure coating (1/5) and Wharton's Jelly (1/5) were used as substrates.

## 2.5. Discussion of Results

PSCs are the most attractive cell source for bioengineering liver tissue because of their potential to be differentiated into all other cell types in the human liver, e.g., HSCs, immune cells, LSECs, etc. However, the stemness of PSCs places greater importance on the biopolymers within the in vitro culture conditions because these become cues for directed differentiation and maturation towards the intended end-targets. In addition, the versatility of a substrate is crucial for its uptake in standard practice and clinical therapy. Ideal substrates should support the differentiation of stem cells into all cell types of the target organ, facilitate the different phases of differentiation without dissociation and replating cells for substrate changes. Substrates should also be easily transferable into humans, e.g., injectable or implantable. This study has identified several fully defined biomaterials used as an alternative to Matrigel-derived substrates in recent years. The properties of these biomaterials are briefly summarised in Table 4.

**Table 4.** Non-matrigel-derived biomaterials used to bioengineer human liver.

Collagen-1 is frequently used in 2D hepatocyte and cholangiocyte differentiation. Nonetheless, it is widely recognised that on its own, it promotes undesired spontaneous differentiation of PSC and is sub-optimal for hepatic organoid culture. Thus, conjugation with other biomaterials is necessary; Matrigel can be added to Collagen-1 to support liver organoid culture (Supplementary Table 1). The use of hyaluronic acid (HA) was featured in two studies: one study differentiated PSCs into hepatocytes using Biomimesys® - HA conjugated to Collagen-1 and Collagen-4 via RDG binding sites [34]. The other study used HA conjugated with cholesterol and dexamethasone to maintain and differentiate LSCs into biliary organoids [35]. Since HA is widely used in medicinal products, it is an interesting biomaterial for liver tissue engineering. However, further research is needed to determine if HA-based matrices can support the multi-cell type differentiation required in liver organogenesis, followed by validation with *in vivo* trials.

A total of four studies used fibronectin to maintain stem cells in culture [36–39]. Four studies used it for hepatocyte differentiation [36,38,40,41], and one study used it to derive LSECs [39]. Indeed, fibronectin seems promising; however, in our experience, it is highly viscous, which makes it very challenging to use in cell culture. In addition, only two studies have reported results of short-term murine experiments. Therefore, more data, including animal studies, are needed. Fibroin is considered a bioactive material [42]; however, it has only been used in one study with NLSCs [43], so its potential is still undetermined.

Human recombinant laminins are a popular alternative to poorly defined xenogenic substrates, although Laminin types significantly affect stem cell biology. Laminin 511 and Laminin 521 are native to the developing embryo [44], and are the only two Laminins that support the long-term clonal expansion of PSCs *in vitro* [45]. Laminin 111 and Laminin 332 are associated with epithelial-to-mesenchymal transition [46,47], especially in ESCs [46]. Therefore, on their own, they may not be suitable for long-term stem cell culture and/or differentiation, although the addition of either laminins to Laminin 511 or Laminin 521 may be a valuable strategy to achieve better end-target cells. Importantly, all available human recombinant laminins are only available in low-concentration aqueous solutions, which are unsuitable for 3D liver bioengineering. As a result, several groups have attempted to conjugate Laminins with various polymeric backbones to form hydrogels. Laminin 511-PIC [48], PIC-LEC[49], Laminin 511-Silk (Supplementary Tables 1 and 2), and Laminin 521 (Biosilk) are recent attempts illustrated above. Nonetheless, robust *in vivo* data on these biomaterials are still outstanding. Notably, at the time of writing, only aqueous Laminin 511 (iMatrix) and Laminin 521 (Biolamina) are available in “good manufacturing grade”. Therefore, an essential strategy for 3D liver bioengineering would be to develop and refine clinical-grade hydrogels (or scaffolds) incorporating Laminin 511 or Laminin 521 with supportive ECMs to enhance end-target phenotypes. Notably, Laminin 411 has previously been reported to enhance liver differentiation [50–52]. However, Laminin 411-containing scaffolds and substrates remain unexplored.

Our searches have also shown that synthetic alternatives such as PEG constructs have been increasingly explored. PEG is usually considered inert; thus, groups have conjugated PEG with bioactive polymers to deliver chemical cues to stem cells with some success. “HepMat” - PEG and

RGD conjugates [53], and other PEG-peptide constructs [54] have been shown to support hepatocyte differentiation, but data on liver/biliary organoids culture and animal experimentation are still outstanding. Similarly, issues apply to most synthetic biomaterials listed in Table 4. Synthetic polymers that have not been conjugated with other bioactive polymers were noted to be used as substrates to reduce cell adhesion and facilitate suspension culture, e.g., Lipidure, PLLA/PCL fibres, Hydrox fibres, etc. Nonetheless, undisclosed proprietary information and non-comprehensive methods significantly hinder the reproducibility and validation of novel synthetic materials.

In summary, approximately 75% of studies that bioengineer liver from PSCs and NLSCs continue to use Matrigel or its derivatives. NLSCs are self-adherent cells that do not require bioactive substrates for liver differentiation but are limited by their lack of pluripotency. Novel techniques to derive other liver cell types from NLSCs can significantly improve liver tissue engineering. Alternatively, hydrogels and scaffolds made from recombinant human proteins are attractive biomaterials to enhance liver derivation from PSCs and LSCS in future research.

### 3. Conclusions

Xenogenic substrates remain predominant biomaterials in liver bioengineering, although human recombinant proteins and synthetic alternatives are gaining popularity. Hyaluronic acid-based hydrogels are a promising alternative, but further research is needed. Laminin 511 and Laminin 521 are available as aqueous clinical-grade solutions only, and hydrogel development with *in vivo* validation is vital for future 3D liver bioengineering efforts and their clinical translation. Synthetic polymers are still underdeveloped and have more milestones to achieve than human recombinant matrices, which have been more extensively researched.

## 4. Materials and Methods

This review is reported in accordance with the recommendations from the PRISMA statement [55].

### 4.1. Data Sources and Searches

**Electronic searches:** A search of PubMed, Medline, Cochrane and Web of Science databases was performed for articles in the last five years between 1 April 2020 to 1 April 2025 using the search terms “stem cells” and “hepatocytes”, “stem cells” and “cholangiocytes”, “liver” and “stem cells”, “liver organoids”, “hepatic organoids”, “biliary organoids”, and “cholangiocyte organoids”. The UK Access Management Federation provided access to journals via Cambridge University.

**Searching in other resources:** The Cambridge University Library was checked for articles that were listed in online search results but not accessible.

### 4.2. Study Selection

**Inclusion criteria:** Only (i) articles in English, (ii) articles with abstracts and full-text links for screening, and (iii) primary research articles were included.

**Exclusion criteria:** Articles (i) not reporting primary research (e.g., reviews, comments, etc.), (ii) not written in English, (iii) lacking a DOI, web-link, and not accessible by the UK Access Management Federation, were excluded. In addition, (iv) veterinary studies (e.g., animal cell lines and experimentation only) and (v) studies not reporting the differentiation of stem cells into liver cells, organoids, or tissue were also excluded.

### 4.3. Data Extraction and Quality Assessment

**Selection of studies:** Three authors (J.O., J.Z.Z. and C.S.) independently reviewed all titles and abstracts and then assessed articles against the inclusion criteria for analysis. A fourth reviewer (A.E.M.) resolved any differences.

**Data extraction and management:** Data were extracted independently by authors J.O., J.Z.Z. and C.S. using a standardised form. The data recorded included the biomaterials used, the stem cell type used, and the end-target cell or tissue type achieved.

**Risk of bias and quality assessment.** All primary research articles that fulfilled the above criteria were screened, minimising the risk of publication bias. The risk of language bias is present but low.

#### 4.4. Data Synthesis and Analysis

**Statistical analysis:** Articles that were successfully screened using the inclusion and exclusion criteria had data extracted and tabulated in Microsoft Excel. Descriptive statistics were used to report data between the stem cell groups.

**Dealing with missing data:** Articles with missing data were omitted in the statistical analyses.

**Assessment of heterogeneity and publication bias:** This was not applicable as meta-analyses were not performed.

**Supplementary Materials:** The following supporting information can be downloaded at the website of this paper posted on Preprints.org.

**Author Contributions:** Conceptualization, J.O.; methodology, J.O.; software, J.O.; validation, J.Z.Z. and C.S.; formal analysis, J.O., J.Z.Z., C.S.; investigation, J.O., J.Z.Z., C.S.; resources, J.O., J.Z.Z., C.S.; data curation, J.O., J.Z.Z., C.S.; writing—original draft preparation, J.O.; writing—review and editing, J.O., J.Z.Z., C.S., A.E.M.; visualization, J.O.; supervision, A.E.M.; project administration, J.O.; funding acquisition, J.O. and A.E.M. All authors have read and agreed to the published version of the manuscript.

**Funding:** This research was partially funded by the W.D. Armstrong Doctoral Fellowship, the School of Technology, University of Cambridge.

**Institutional Review Board Statement:** Not applicable.

**Informed Consent Statement:** Not applicable.

**Data Availability Statement:** The original contributions presented in this study are included in the article/supplementary material. Further inquiries can be directed to the corresponding author(s).

**Acknowledgments:** Nil.

**Conflicts of Interest:** The authors declare that they have no conflicts of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

## Abbreviations

The following abbreviations are used in this manuscript:

MDPI	Multidisciplinary Digital Publishing Institute
DOAJ	Directory of open access journals
2D	Two dimensional
3D	Three dimensional
DED	Definitive Endoderm Differentiation
ESCs	Embryonic Stem Cells
GelMA	Gelatin Methacryloyl
GFR	Growth Factor Reduced
HA	Hyaluronic acid
iPSCs	Induced Pluripotent Stem Cells
LIC-LEC	PIC-Laminin 111-Entactin-Complex
LSCs	Liver Stem Cells
LSECs	Liver Sinusoidal Endothelial Cells
MSCs	Mesenchymal Stem Cells

NLSCs	Non-Liver Stem Cells
PSCs	Pluripotent Stem Cells
PAA	Polyacrylamide
PEG	Polyethylene Glycol
PIC	Polyisocyanopeptides
PLLA/PCL	Poly-L-lactic acid/poly ( $\epsilon$ -caprolactone)
PCL-Gel-HA	Poly $\epsilon$ -caprolactone-gelatin-hyaluronic acid
