**Abstract:** Several empirical studies indicate that the lack of financing is one of the main barriers that affects the economic growth of small and medium enterprises (SMEs). The main objective of this investigation was to determine to what extent the economic sector; enterprise size; the characteristics inherent to the enterprise; legal status; the variables linked to the performance of the enterprise; and the attributes of the owner influence the access to bank financing of SMEs in Mexico. Using a discrete response probit regression model, the impact of enterprises characteristics on the probability of obtaining a bank loan was determined. The data collected is from the Enterprise Surveys of Mexico, carried out by the World Bank. The sample of 1,480 enterprises is representative by enterprise size, by economic sector, and by region. The research has a quantitative approach with a correlational scope and a non-experimental and transectional design. One of the main results highlights that the determinants with the greatest influence on access to bank financing are: age, the small size, foreign participation, and the manufacturing sector. These results are consistent with other empirical studies, as well as with the pecking order theory and the financial life cycle theory.

Keywords: Determinants; access; bank financing; SMEs; probit model

# 1. Introduction

SMEs are a key element for the economic development of Mexico, they represent 4.9% of all enterprises in the country, provide 30.7% of jobs and contribute 31% of added value (National Institute of Statistic and Geography, 2020). However, various empirical studies indicate that the lack of financing is one of the main barriers that affects the economic growth of SMEs and that the smallest enterprises are the most affected by this limitation. According to Kumar et al. (2020) studies on the capital structure of SMEs have generated great relevance in recent years due to the economic importance of these enterprises for the countries and because most of the research on capital structure has been carried out only in large enterprises.

According to the quarterly survey of conjunctural evaluation of the credit market, there is a large gap in access to bank financing between SMEs and large enterprises. SMEs with bank debt as of December 2021 represented 35.3%, while in large enterprises it was 56.1%. It is also highlighted that SMEs report having greater limitations than large enterprises to access new bank loans (Bank of Mexico, 2022a; 2022b).

Among the modern theories that address research on the behavior of enterprises in relation to the request for financing (credit demand) is the pecking order theory and the financial life cycle theory, both theories have been studied in the context of the SMEs. There are several factors that limit access to bank financing, which can be classified into three aspects: a) those related to the country's economy; b) those related to the banking system; and c) those related to the characteristics inherent to the enterprises. In this sense, the various investigations on this object of study are focused from the perspective of supply or demand for bank credit. Therefore, this research focuses on the study of

the determinants of bank financing from the scope of the characteristics of SMEs and the attributes of their entrepreneurs, that is, from the perspective of credit demand.

The general objective was to determine to what extent the economic sector; the enterprise size; the characteristics inherent to the enterprises; legal status; the variables linked to the performance of the enterprise; and the attributes of the owner influence the access to bank financing of SMEs in Mexico.

Based on the binary probit regression models and the profile analysis, it was identified that the variables with the greatest influence on the probability of obtaining a bank loan are the age of the enterprise, the small size, foreign participation, and the manufacturing sector. In other words, younger, small, foreign-owned, and non-manufacturing enterprises are the least probability to access bank financing. These results are consistent with other empirical studies analyzed in this research, as well as with pecking order theory and financial life cycle theory.

# 2. Literature review

# 2.1. Theoretical framework of business financing

# 2.1.1. Pecking order theory

In the pecking order theory, a hierarchical order of preferences for enterprises financing is established: first, they are financed through internal sources such as retained earnings and partner contributions; secondly, if they need additional resources, they will request bank loans; and ultimately, they issue new equity (Donaldson, 1961; Myers, 1984; Myers and Majluf, 1984). It is considered that this theory applies to small enterprises due to their restricted access to the capital market caused by the little information available, which makes it impossible to know the quality of the management of this type of enterprise, which is why lenders choose to protect your resources through short-term repayments as a measure to protect your investment. In this sense, small entrepreneurs are forced to obtain short-term business loans, but at a high cost (Chittenden et al., 1996).

López-Gracia and Sogorb-Mira (2008) point out that SMEs apply the pecking order theory in financing decisions. This order is directed by the financial sources that are subject to less information costs and less risk. Internal funds are the main source of financing, followed by lower-risk short-term debt and then higher-risk long-term debt. The last option is to resort to new capital, which is the source of financing with high information costs.

The assumptions that support the financial hierarchy theory offer a better explanation of the capital structure adopted by SMEs. The asymmetry of information, as well as the motivation of current shareholders to maintain control and corporate ownership are relevant factors that condition the choice of financing sources (Ferrer and Tresierra, 2009). In the same sense, Yazdanfar and Öhman (2016) indicate that the owners or managers of SMEs choose to be autonomous and maintain control of their enterprises, which is why they follow a hierarchical order in financing decisions, preferring first internal sources that the external ones.

In this sense, the limitation that SMEs have to access financing originates from the information asymmetry problems between borrowers and lenders, which implies information costs derived from these asymmetries. SMEs prefer internal sources of financing that imply less information costs and less risk (Briozzo, Vigier and Martinez, 2016). Due to the difficulty in accessing long-term sources of financing, there is a higher probability that young SMEs follow the pecking order theory than the compensation theory predicts (Serrasqueiro and Nunes, 2012).

# 2.1.2. Financial Life Cycle Theory

The Financial Life Cycle Theory establishes that the financial needs of enterprises change as their life stages progress. As the firm grows and ages, gains more experience, and the availability of information increases, its financial needs and financing options change (Berger and Udell, 1998). During the cycle of financial growth and derived from the reduction of information asymmetries, the

enterprise has changing financial needs and can resort to other sources, in addition to the internal ones, such as venture capital, loans from financial institutions, starting with the short term and later in the long term (Briozzo, Vigier, Castillo et al., 2016).

Berger and Udell (1998) indicate that enterprises develop through a financial growth cycle paradigm in which different capital structures are optimal at different points in the cycle. In this way, when enterprises are young and small, they are less transparent in their financial information, so they are financed with their own resources, resources from family and friends. As it grows, access to commercial credit or through business angels increases. Over time, if the enterprise continues to grow, it may turn to venture capital institutions, the debt market, or public capital (Guercio et al., 2017).

Briozzo, Vigier, Castillo et al. (2016) point out that there is a relationship between the life cycle of enterprises and their owners. As enterprises and their owners grow, information asymmetries are reduced, making access to financing easier. On the other hand, the older the risk aversion and the personal costs of bankruptcy increase, factors that discourage the use of external financing.

# 2.2. Variables of bank financing of SMEs

# 2.2.1. Size of the enterprise

The size of the enterprise indicates that the more developed or expanded an enterprise is, the more likely it will be able to generate sufficient resources to repay the loan. Likewise, larger enterprises have a greater capacity to acquire more assets as collateral for the loans obtained, which is why it has been shown to have a positive relationship with the possibility of accessing a loan (Botello, 2015).

Beck and Demirgüc-Kunt (2006) indicate that in countries with fixed transaction costs and information asymmetries, small enterprises that demand smaller loans face higher transaction costs and higher risk premiums because they are generally more opaque and they have fewer guarantees to offer. This is reflected in financing patterns: small enterprises finance less of their investment and working capital with bank financing compared to large enterprises. By contrast, smaller enterprises finance a greater share of the investment with informal sources such as moneylenders, family, and friends.

Mac an Bhaird and Lucey (2010) found that the larger the enterprise, the greater the probability of accessing external financing. In addition, Petersen, and Rajan (1994) and Hutchinson (2004) identified that the size of the enterprise is positively related to the indebtedness of the enterprises. In the same sense, Rao et al. (2018) agree that the size of the enterprises is positively related to indebtedness because larger enterprises have more access to external financing sources and the cost of acquiring credit is lower for larger enterprises than for small enterprises. The debt of small enterprises is proportionally less than that issued by larger enterprises due to some factors such as: higher bankruptcy costs, higher agency costs and higher costs of monitoring information asymmetries, among others (Michaelas et al., 1999).

#### 2.2.2. Age of the enterprise

The age of the enterprise is a controversial variable. On the one hand, Petersen and Rajan (1994) identified a negative relationship between the seniority of SMEs and access to bank financing. On the other hand, Gregory et al. (2005) and Bougheas et al. (2006) indicate that there is a positive relationship.

In the same vein, Yazdanfar and Öhman (2016) point out that the results on the relationship between the enterprise age and debt are contradictory. On the one hand, enterprises can improve their competitiveness and reputation over time, which increases the probability of access to credit for older enterprises. On the other hand, enterprises can increase retained earnings over time, making older enterprises more probability to use them as a source of internal financing and require less external financing.

Rao et al. (2018) indicate that the age of the enterprise is positively related to financing. Older enterprises are more probability to obtain credit, while newer enterprises depend mainly on their internal sources of financing because they do not request external financing due to their low credibility in the credit market.

Serrasqueiro and Nunes (2012) indicate that the age of the enterprise is an influential factor that affects access to external financing, young SMEs on average had a higher short-term debt than older SMEs. On the other hand, young SMEs on average had lower long-term debt than older enterprises.

Mac an Bhaird and Lucey (2010) point out that older SMEs are less dependent on external financing, because as they age tend to use retained earnings more and more as internal financing. In the same vein, Hall et al. (2004) indicate that the older an enterprise is, it will be able to accumulate more funds and will need less financing. In other words, a young enterprise will not have had time to accumulate funds and will be forced to apply for credit. Therefore, age is negatively related to financing in both the short and long term.

On the other hand, it has been shown that younger SMEs use more internal financing instead of bank loans; in contrast, as the age of the firm increases, the proportion of bank loans gradually increases and informal financing decreases (Nizaeva and Coskun, 2019). Now, it is likely that the financial cycles of enterprises and the life cycles of owners are connected, sometimes with opposite effects. For example, information asymmetries reduce with increasing age of enterprises, resulting in greater access to external financing, while risk aversion and the cost of personal bankruptcy increase with the age of the entrepreneur, which implies a lower desire for debt (Briozzo and Vigier, 2014).

Younger SMEs have less experience and a lower track record of success than older enterprises, which makes it difficult for them to obtain bank credit (Bougheas et al., 2006 and Andrieu et al., 2018). Consolidated enterprises in a market with solid productive structures offer banking institutions sufficient guarantees to cover bank loans in the future, so the older the enterprises, the greater the probability of access to bank financing (Botello, 2015).

Berger and Udell (1998) with a focus on the financial life cycle, infer that enterprises tend to depend more and more on bank credit during their early stages of life, but that they use less bank credit as they get older. La Rocca et al. (2011) infer that small enterprises in Italy have high levels of debt early in their life cycle, but this debt ratio declines in later life cycle stages as firms accumulate retained earnings that they will use as a source of financing.

#### 2.2.3. Economic sector

The economic sector where SMEs develop also influences access to external financing; various empirical studies have shown that SMEs in the service sector have greater restrictions to access external financing (Guercio et al., 2017). In the same sense, Michaelas et al. (1999) indicate that the industry influences on the total level of debt in small enterprises, as well as on the maturity structure of the debt.

SMEs in the service sector face more financial constraints compared to manufacturing SMEs, this may be due to the difficulty for lenders to assess intangible assets compared to tangible assets (Cressy and Olofsson, 1997). Briozzo and Vigier (2014) indicate that enterprises in the manufacturing sector have more assets that can serve as collateral for a loan. This factor reduces information asymmetries between the enterprise and the lenders, so these enterprises have greater probability of access to credit. Baker et al. (2020) agrees that SMEs in the manufacturing sector with tangible assets are more likely to obtain external financing than enterprises in the service sector with fewer tangible assets. In addition, manufacturing SMEs use long-term financing and other sources of financing, while service SMEs use short-term financing.

# 2.2.4. Legal status

According to Guercio et al. (2020), an enterprise incorporated with a legal form that limits patrimonial responsibility, such as corporations or limited liability enterprises, influence on access to credit because they are more transparent, in relation to those enterprises that do not limit patrimonial responsibility.

Briozzo, Vigier, Castillo et al. (2016) identified that enterprises with limited liability use long-term credits more frequently than those enterprises that do not have this legal form; this result also presents significant differences and coincides with the compensation theory. In addition, they infer that banks consider limited liability as a positive factor that indicates credibility, formality of operations, and represents signs of potential growth. Therefore, they identify a positive relationship between limited liability and access to bank credit.

In the same vein, Baker et al. (2020) point out that limited liability enterprises have a greater preference for all kinds of financing sources than sole proprietorships. Briozzo and Vigier (2014) in their research indicate that enterprises that are constituted as limited liability enterprises are expected to have more attractive bank credit opportunities. On the other hand, Demirgüç-Kunt et al. (2006) in their research found that enterprises report fewer financial obstacles to their growth than unincorporated enterprises, and this advantage is greater in countries with more developed institutions and favorable business environments.

# 2.2.5. Foreign participation and export capacity

Foreign ownership is a variable that influences the search for financing because foreign parent enterprises, which are likely to be large enterprises, may be the main source of financing for subsidiaries, reducing the need for external financing (Xiang et al., 2015). Foreign-owned or multinational enterprises are expected to face fewer financial obstacles because they have easier access to international sources of external financing (Beck, Demirgüç-Kunt, Laeven et al., 2006).

On the other hand, Pasquini and De Giovanni (2010) showed that enterprises are more likely to access external financing if they export part or all their sales. Baker et al. (2020) mention that Indian SMEs that have export activity are influenced in the use of their financing sources.

# 2.2.6. Entrepreneur attributes

In general, enterprises with managers with little experience and a low level of education are more likely to have restrictions on accessing external financing (Cowling et al., 2016). Baker et al. (2020) mention that older managers or owners' resort to more formal debt (short-term and long-term financing) than their younger counterparts. Also, owners with significant work experience use more short-term financing or other forms of financing than those with little experience.

Various studies emphasize that women-owned enterprises face more difficulties in accessing business credit (Chaudhuri et al., 2020). Also, enterprises managed women are less probability to access credit and have to pay higher interest rates (Muravyev et al., 2009; Presbitero et al., 2014).

According to Baker et al. (2020) male managers or owners choose to use internal financing sources, as well as credits, however, women use other forms of financing more, such as commercial credits, moneylender resources, loans from relatives and friends, as well as funds from other enterprises. However, in other studies carried out to analyze the effect of gender on access to formal financing, they did not identify evidence of gender discrimination in obtaining credit (Aterido et al., 2013; Bardasi et al., 2011).

#### 2.3. Empirical studies on the determinants of bank financing

This section briefly presents, in chronological order, the most significant empirical studies on the determinants of bank financing of SMEs developed in recent decades internationally. Table A1 in the appendix presents a summary indicating the sample (country, size, and period) of the study, the variables of interest related to this research, the methodology, and the main results.

Despite the great diversity of empirical studies, the only one that was identified in the context of SMEs in Mexico was the study by Gómez et al., (2009), whose objective was to identify the restrictions in the approval of a bank loan, it focused on the ambit of credit supply. In addition, its sample was limited to 128 SMEs in the manufacturing sector of Puebla, Mexico between 2007 and 2008. In contrast, this research focuses on the field of credit demand with a sample of 1,480 representative enterprises by enterprise size, by region and by economic sector of Mexico.

# 3. Data and Methodology

# 3.1. Sample and Data

The data collection instrument used is the questionnaire of the main module of the Enterprise Surveys of Mexico 2010, carried out by the World Bank through face-to-face interviews with managers and owners of enterprises in Mexico between the 17th of August 2010 and June 30, 2011 (World Bank, 2011). At the time of carrying out this research, this survey was the last applied in Mexico and includes the necessary data to develop the objectives of this research.

The target population it was made up of enterprises with five or more employees in the manufacturing, commerce, and services sectors, located in the eight regions of Mexico with the greatest economic activity. The sample was selected through stratified random sampling. The final sample was 1,480 enterprises, enough large and representative by enterprise size (small, medium, and large), by economic sector (manufacturing, commerce, and services) and by geographic region (World Bank, 2011).

#### 3.2. Variables

The variables were defined conceptually in accordance with the provisions of the items of the main module of the Enterprise Surveys of Mexico 2010 (World Bank, 2010). The operational definitions contribute to establishing the way in which the research variables will be measured, see details in Table 1.

**Table 1.** Conceptual and operational definitions of the variables.

	•	-
Item	Variables	Concept definition Operational definition

# 3.3. Research hypothesis

The central hypothesis that guided the research was in the sense of affirming that the economic sector; the enterprise size; the characteristics inherent to the enterprise; legal status; the variables linked to the performance of the enterprise; and the attributes of the owner significantly influence the access to bank financing of SMEs in Mexico. In this sense, the operational hypotheses were:

• *H*<sub>1</sub>. *Economic sector*. Enterprises in the manufacturing sector are more likely to access bank loans than those in other sectors. In contrast, those in the services sector are less likely to have access to bank financing than those in other sectors.

- 8
- *H*<sub>2</sub>. *Enterprise size*. The larger the enterprise, the greater the access to bank financing. Small enterprises are less likely to access bank loans.
- *H*<sub>3</sub>. *Enterprise age*. The older the enterprises, the greater the access to bank financing. Older enterprises are more likely to access bank loans.
- *H*<sub>4</sub>. *Foreign participation*. Foreign-owned enterprises are less likely to use bank credit.
- *H*<sub>5</sub>. *Legal status*. Enterprises legally incorporated as society or associations are more likely to access bank loans than enterprises that have a sole owner.
- *H*<sub>6</sub>. *Exporter*. Exporting enterprises are more likely to use bank loans.
- *H*<sub>7</sub>. *Checking/saving account*. Enterprises that have a checking or savings account are more likely to access bank financing.
- *H*<sub>8</sub>. *Annual sales*. The higher the annual sales of the enterprises, the greater the access to bank credits.
- *H*<sub>9</sub>. *Permanent employees*. The more full-time permanent employees an enterprise has, the greater the probability of accessing bank financing.
- *H*<sub>10</sub>. *Manager female*. Enterprises in which the general manager is a woman are less likely to access bank loans.
- *H*<sub>11</sub>. *Manager experience*. Enterprises in which the general manager has more experience are more likely to use bank financing.

# 3.4. Research design

Using a discrete response probit regression model, the degree of impact that the independent or explanatory variables have on the probability of obtaining a bank loan was determined, so the study has a quantitative approach with a correlational scope. Likewise, the research design is non-experimental and cross-sectional (Hernández-Sampieri and Mendoza, 2018).

### 4. Empirical results

#### 4.1. Characterization of the sample and descriptive statistics

Table 2 shows the integration of the sample of surveyed enterprises. Likewise, the description of the binary independent variables with respect to the dependent variable is presented. In general, only 48.3% of the enterprises surveyed indicated that they had a bank loan. From these data, some a priori significant differences can be observed.

**Table 2.** Binary variables by group of enterprises (with and without bank credit).

	Samp	le		Bank c	redit	
Independent variable	Total	%	No	%	Yes	%
Manufacturing	1145	77.8%	569	49.7%	576	50.3%
Commerce	144	9.8%	83	57.6%	61	42.4%
Services	182	12.4%	109	59.9%	73	40.1%
	1471	100%	761	51.7%	710	48.3%
Small	358	24.3%	251	70.1%	107	29.9%
Medium	349	23.7%	182	52.1%	167	47.9%

General manager is Female	160	10.9%	96	60.0%	64	40.0%

	1470	100%	761	51.8%	709	48.2%
Non-exporter	1160	78.9%	636	54.8%	524	45.2%
Exporter	311	21.1%	125	40.2%	186	59.8%
	1471	100%	761	51.7%	710	48.3%
No checking/savings account	506	34.5%	299	59.1%	207	40.9%
With checking/savings account	961	65.5%	460	47.9%	501	52.1%
	1467	100%	759	51.7%	708	48.3%

Source: Own elaboration based on data analysis.

Table 3 shows the relationship of the quantitative independent variables with respect to having a credit or bank loan. For example, the average age of enterprises that have a bank loan is 25.9 years (higher than the average of the sample, which is 24), while those that do not have it is 22.2 years.

Table 3. Quantitative variables by group of enterprises (with and without bank credit).

		Bank o	credit
Independent variable	Sample average	No	Yes
Enterprise age (average years)	24.0	22.2	25.9
Manager experience (average years)	23.0	22.3	23.8
Permanent employees (average number)	216.2	170.0	267.8
Annual sales Quantile 1 (%)		72.4%	27.6%
Quantile 2 (%)		49.4%	50.6%
Quantile 3 (%)		43.2%	56.8%
Quantile 4 (%)		41.3%	58.7%

Source: Own elaboration based on data analysis.

Table 4 presents the summary of the basic descriptive statistical analyzes of each one of the independent variables.

**Table 4.** Summary of basic descriptive statistics of the variables.

Variable	Obs.	Minimum	Maximum	Mean	Standard deviation

Table A2 in the appendix presents the correlation matrix to determine the relationship or dependency that exists between the independent variables of the research. The results of these correlations are consistent with the context of the growth of Mexican enterprises, measured through their annual sales and permanent employees, as well as their legal status. A larger share of small enterprises is managed by a single owner, with low annual sales and few employees, compared to large enterprises. In fact, the last two criteria (annual sales and employees) are used in Mexico to classify enterprises by size.

#### 4.3. Multivariate analysis: Probit regression model

To determine which enterprise characteristics explain whether or not it has a bank loan, we perform a multivariate analysis using a probit regression model. The proposed model is a binary probit, which is used when the dependent variable is dichotomous, which is why it is considered a binary or discrete response model and its main objective is to determine the response probability (Wooldridge, 2010). Therefore, the following equation of the probit model is proposed to determine the probability that an enterprise will access a bank loan:

```
Y = \alpha + \beta 1 * Manufacturing + \beta 2 * Commerce + \beta 3 * Services + \beta 4 * Small + \beta 5 * Medium + \beta 6
* Large + \beta 7 * Age + \beta 8 * Foreign + \beta 9 * Single owner + \beta 10 * Society or association + \beta 11
* Exporter + \beta 12 * Checking/saving account + \beta 13 * Annual Sales + \beta 14 * Permanent employees + \beta 15 * Manager female + β 16 * Manager experience + <math>\epsilon i (1)
```

where Y = Bank credit, is the explained or binary dependent variable, which takes the value of 1 (one) if the enterprise has a bank credit and 0 (zero) otherwise. The explanatory variables that can potentially be incorporated into the model represent various specific characteristics (defined in Table 1) of the enterprise that determine access to bank credit.

Tests were carried out with different variables alternatively, starting from the broadest model that included all the potentially explanatory variables until reaching other more restricted models that included only the significant variables according to estimated models or previous empirical studies. Based on various combinations, more than 60 models were determined. Table A3 in the appendix presents the summary of the main results of the 10 models that were considered most relevant. According to the regression models, the variables that are considered most significant determinants or predictors for obtaining a bank loan are: manufacturing sector, services sector, small size, age of the enterprise, foreign participation, checking-savings account, and annual sales.

Belonging to the manufacturing sector is a robust predictor, in most models it has a significance of 99% and the coefficients have a probability greater than 22% with a positive effect. On the other hand, the services variable has a significance of 99% in most of the models and its coefficients have a probability greater than 26% with a negative effect. For example, in the M1 model, an enterprise that operates in the manufacturing sector has a 23.42% higher probability of accessing a bank loan than an enterprise that does not belong to said sector; while in the M2 model, a service sector enterprise is 26.26% less likely to obtain a loan than its counterparts. The small size variable is one of the most robust predictors, a small enterprise has between 30.08% and 40.51% less probability of accessing a bank loan than its counterparts and in all models, it has a significance of 99%.

The age of the enterprise is one of the most solid predictors of bank credit, in most models it has a significance of 95% and all its coefficients resulted with the expected positive effect. Foreign participation is one of the most robust determinants, in all models it has a significance of 99% and with estimated probabilities greater than 49% with a negative effect. Holding a checking or savings account is considered another determinant, although not as robust because it only has a significance of 90% and with estimated probabilities greater than 13.97% with a positive effect. Annual sales is a variable with mixed results, in some models it has a significance of 99%, while in others it is 90% and in the models M1, M4 and M6 it is not significant. However, it is considered a determinant of bank financing because its estimated probabilities were greater than 44% and with the expected positive sign. Regarding the other variables, they are not considered determinants of access to bank loans because they were not significant in the regression models in which they were included.

Regarding the goodness-of-fit measures of the models, McFadden's R2 is low; however, these models are considered to have acceptable predictive power because the percentage of correct predictions in relation to the total number of observations is greater than 61% in all models, so all are classified as if they were 1. Likewise, in models with discrete response, what is important is that the expected signs of the regression coefficients are in harmony with other studies and coincide in practice with the business context (Gujarati and Porter, 2010).

### 4.4. Profiles Analysis

Subsequently, the three most relevant models (M1, M2 and M3) were selected to determine the various profiles with their estimated probability that an enterprise has a bank loan based on the independent variables that were significant in each model. For reasons of space, only the profiles of the M1 model are shown in Table A4 of the appendix.

In determining the estimated probability of profile 1 of each model, the significant variables are considered with a reference value. In the binary variables, the value of 1 (one) was taken, which indicates that they do have said characteristic; in the age variable, the average in years of the sample was taken; and in annual sales, the upper value of quantile 1 was taken. In the probabilities of the other profiles (Profile 2 to Profile X) the values of the significant variables of profile 1 are maintained and only the value of the variable of interest is modified that you want to change in each profile; in the case of binary variables, it was changed with a value of 0 (zero) which indicates that they do not have said characteristic; in the age variable it was changed to other values progressively; and in annual sales, it was changed by the value of quantiles 2, 3, and 4. The estimated probabilities of each profile are compared by a difference with the probability of profile 1 to determine the importance of each variable.

According to profile 1 of the M1 model, a small enterprise that belongs to the manufacturing sector, with 24 years of life (average of the sample), with foreign participation and with a bank account has a probability of having a bank credit of 51.58%. Starting from profile 1 of each model, other alternate profiles were created to analyze the influence of each independent variable on access to bank financing.

In the profiles of the M1 model in Table A4 of the appendix, age is shown as the determinant with the greatest impact on access to bank financing. According to profile 1, the probability that an enterprise with 24-year-old has a bank loan is 51.58%, while when changing to one year (profile 4) it only has a probability of 3.21%, that is, 48.36% less of probability. As age increases, the probability of having a bank loan gradually increases. The second most relevant variable is foreign participation; the probability of having a bank loan in profile 1 is 51.58%, while an enterprise that does not have one (profile 9) is 71.35%, that is, 19.77% more probability. The third and fourth variables with the greatest influence are small size and manufacturing, respectively.

#### 5. Discussion and conclusions

#### 5.1. Contributions of the research

Based on the predictive power acceptable of the estimated binary probit regression models, the operational hypotheses were contrasted, for which the following conclusions are established:

- H<sub>1</sub>. Economic sector. It is confirmed that enterprises in the manufacturing sector are more
  probability to access bank loans than enterprises in other economic sectors; while those in the
  service sector are the least likely to have access to bank financing. In the same way, it is
  confirmed that the commerce variable does not have a significant relationship with the
  dependent variable, as had been proposed in the hypothesis.
- *H*<sub>2</sub>. *Enterprise size*. It was confirmed that small enterprises are less probability to access bank loans. Regarding the large variable, the hypothesis that the larger the companies, the greater the access to bank financing is rejected. On the other hand, it is confirmed that the medium enterprise variable does not have a significant relationship with the dependent variable.

- *H*<sub>3</sub>. *Enterprise age*. It is confirmed that older enterprises are more probability to access bank financing. The age of the enterprise is the most robust predictor of bank credit, according to the profile analysis, as the age of the enterprise increases, the probability of acquiring a bank loan increases progressively.
- *H*<sub>4</sub>. *Foreign participation*. It confirms that foreign owned enterprises are less likely to obtain bank financing because foreign parent enterprises are the main source of financing for their subsidiaries.
- *H*<sub>5</sub>. *Legal status*. This hypothesis is partially confirmed. On the one hand, it is rejected that enterprises legally constituted as societies or associations are more likely to use bank financing than enterprises that have a sole owner because it did not result significantly in any of the regression models in which this variable was included. On the other hand, it is confirmed that the single owner variable does not have a significant influence on access to bank credit.
- *H*<sub>6</sub>. *Exporter*. The hypothesis that there is a positive relationship between exporting enterprises and the probability of using bank loans is rejected, it was only 90% significant in models M2 and M8, however, in all other models it was not significant.
- *H*<sub>7</sub>. *Checking/saving account*. It is confirmed that enterprises that have a checking or savings account are more likely to acquire bank loans than an enterprise that does not have such an account.
- *H*<sub>8</sub>. *Annual sales*. It is confirmed that enterprises with higher annual sales are more likely to use bank financing.
- *Hypothesis H*<sub>9</sub>, *H*<sub>10</sub>, and *H*<sub>11</sub>. The hypotheses H<sub>9</sub>, H<sub>10</sub>, and H<sub>11</sub> are rejected, the regression models indicate that there is no significant relationship between the independent variables (permanent employees, manager female, and experience of the general manager) with the dependent variable, so they are not considered determinants of the access to bank financing.

In summary, based on the profile analysis, it was concluded that the enterprise age is the determinant with the greatest impact on the probability of having a bank loan, it is followed by other predictors such as foreign participation, small size, and the manufacturing sector. Annual sales also have an influence on the dependent variable. However, it is recommended to treat this result with reserve in future research because in the regression models it had mixed results, in some models it has a significance of 99%, while in others it was 90% and in others it was not significant, therefore which is not considered a robust determinant of bank financing.

Based on the conclusions of the previous results, Table 5 presents a summary of the comparison of the hypotheses (expected effect) with the empirical results (real effect) on the probability of accessing bank loans. Likewise, both the empirical studies that coincide with the results and those that do not coincide are shown.

Based on the probit regression models and the profiles analysis, it is concluded that age, small size, foreign participation, and manufacturing sector are the most influential determinants in bank financing; this means that younger, small, foreign-owned, and non-manufacturing firms are the least probability to obtain bank credit.

Additionally, it is concluded that the financial hierarchy theory applies to the financing decisions of SMEs because when they are young, they prefer internal sources of financing that imply lower information costs and less risk, as well as due to their restricted access to external sources. The financial life cycle theory also applies to SMEs because when they are young and small, they are less transparent in their information, so they are mainly financed with their own funds. However, as the enterprise grows and becomes older, it gains more experience and the opacity of information decreases, so its financial needs change.

It should be noted that this research is pioneering because through a discrete response probit regression model, as well as through profile analysis, the variables with the greatest influence on the probability of obtaining a bank loan were identified. As far as is known, there are no other studies that address this issue with this methodology in Mexico. Due to the above, this research is relevant because it provides findings on the determinants of access to bank financing in SMEs in Mexico that contribute to solving this complex problem.

#### 5.2. Research recommendations and limitations

Business financing in Mexico is a challenge that must be addressed urgently. A fundamental challenge is to understand that SMEs have very different structures from large enterprises and that the sources of financing to capitalize this type of business must be more accessible and with special mechanisms, so it is recommended to implement innovative public policies that favor access financing under the best conditions for this business sector.

Likewise, it is recommended that the banking system, government, and enterprises implement permanent training campaigns on financial education aimed at owners and managers of SMEs and micro-enterprises to encourage their participation in the financial sector, as well as learn about other alternatives for financing that contributes to improve their competitiveness.

One of the limitations of this study is related to the database, which was collected between 2010 and 2011 through the World Bank survey of enterprises. However, data collection through a direct survey was not considered feasible due to the high costs involved. Likewise, an extensive search of secondary data was carried out and it was identified that the World Bank survey of enterprises was the last one carried out for Mexico, and it is also the most appropriate according to the available data and the objectives of this research. Once the World Bank updates the enterprises survey for Mexico, it is recommended to replicate this research to have more recent data and compare the findings with this study.

Note: The coefficients of each variable are reported in the first row. QML standard deviations are reported in parentheses in the second row of each variable. To measure the degree of significance, the following is used: \* for a confidence level of 90%; \*\* for 95% confidence; and \*\*\* for 99% confidence. For probit, the R2 is the McFadden pseudo-R2. An empty cell indicates that this variable was not included in the model. Source: Own elaboration based on the regression models estimated in Gretl.

**Table A4.** Profiles of the M1 probit model.

Dependent variable: Bank credit

											Profil 1	Profil 2	Profil 3	Profile 4	Profile 5	Profile 6	Profile 7	Profile 8	Profile 9	Profile 10
