Abstract: The performance of modified electrode of nanocomposite film consisting of polypyrrole-chitosan-titanium dioxide (Ppy-CS-TiO₂) has been explored as non-enzymatic glucose biosensors. The synergy effect of TiO₂ nanoparticles and conducting polymer on the current response of electrode resulted in higher sensitivity for nanocomposite modified electrode. The incorporation of TiO₂ nanoparticles in the nanocomposite films were confirmed by XPS spectra. The FESEM and HR-TEM provided more evidences for the presence of TiO₂ in Ppy-CS structure. Glucose biosensing properties were determined by amperometry and cyclic voltammetry (CV) methods. The interfacial properties of nanocomposite electrodes were studied by electrochemical impedance spectroscopy (EIS). The developed biosensors showed a good sensitivity over the linear range of 1-14 mM with a detection limit of 614 μM for glucose. It also exhibited good selectivity and long term stability with no interference effect. The Ppy-CS-TiO₂ nanocomposites film presented high electron transfer kinetics.

Keywords: nanomaterials; non-enzymatic glucose biosensors; nanocomposites; electrodeposition; titanium dioxide nanocomposite; XPS; EIS.

1. Introduction

The organic-inorganic nanocomposite materials concerned widespread attention because of realizing the combined properties of organic and inorganic components in the same material [1-3]. Conductive polymers and metal oxide nanocomposites with nanoscale dimensions are of special interest for improving the properties of sensors [4-11]. Metals oxides, such as copper oxide (CuO), titanium oxide (TiO₂), iron oxide (Fe₃O₄) are very often recognised as nano oxides in their native or modified forms for the oxidation of glucose [12-14]. Although glucose oxidase (GOx)-based enzymatic biosensors have been usually used for the detection of blood glucose since 1962 [15], however, these enzyme-based sensors show the possible thermal and chemical deformation during fabrication, storage and so on [16,17]. Therefore, non-enzymatic glucose sensors have received great interests particularly through modification of the bare electrode surface with some metal oxide nanoparticles. Modified nanoparticles electrode provides higher surface area improving electron transfer between sensing reaction and electrode [18-21].

Among the metal oxide nanoparticles, titanium dioxide nanoparticles (TiO₂) NPs have been exploited as a potential material for numerous applications because of their unique properties, including high surface area with high catalytic efficiency [22,23]. The importance of these properties is to enhance the interaction between biomolecules and surface of electrode due to higher accessibility

of target molecules to the sensing area [24-26] thus, newer efforts include metal oxide and conducting polymers as non-enzymatic glucose sensors.

This paper describes the development of nanocomposite films of polypyrrole-chitosan-titanium dioxide nanoparticles (Ppy-CS-TiO₂) on the ITO glass electrode for the detection of glucose, which has not been reported before as non-enzymatic glucose sensors involving TiO₂ as the nanoparticle. The role of TiO₂ as a nanoparticle could enhance the sensing performances such as sensitivity, stability, and selectivity in glucose biosensors by the prepared Ppy-CS-TiO₂ electrode has been reported here.

2. Results and Discussion

The presence of TiO₂ nanoparticles in the nanocomposite films was confirmed by XPS. The XPS wide-scan spectra are presented in Figure 1 (a) and the XPS quantitative elemental analysis of narrow scan is presented in Figure 1 (b), (c), (d) and (e)) respectively. For pyrrole, C 1s around (285) eV, N 1s around (400) eV, O 1s around (531) eV. The main carbon peak at 286.2 eV in chitosan corresponds to carbon bonded with both the hydroxyl group and nitrogen. In the carbon-related spectrum, two other significant peaks were appearing, which can be assigned to carbon to carbon single bonds (284.8) eV and carbonyl groups (approx. 287.8 eV), both are present in the chitosan structure. Moreover, the minor peak in the position of approximately (288.0) eV is noticeable. This peak can be observed as unreacted acidic acid hydroxyl groups (-COO) in Figure 1 (b) [27]. The high-resolution spectrum, however, exposes at least two chemically different nitrogen. The stronger peak at (399.8) eV can be assigned to neutral -N- whereas the higher binding energy peak at (401.0) eV is assigned to the oxidized -N⁺ moieties. These values are considered for the conducting of Ppy associated well with the value obtained electrochemically as seen in Figure 1 (d) [28]. The O1s peak for this nanocomposite appears with a split at 530.6 eV in Figure 1 (c) and represents the lattice oxygen. It is shifted slightly compared to database values [29]. It is expected that this shift is caused by the particle diameter of less than 20 nm. Another O1s peak shows at 532.5 eV and is due to the surface oxygen. In this case, the energy is higher compared to the bulk since there are open bonds. Since this material is of nanometer-size, it has a large specific surface area which increases the ratio of surface to bulk oxygen. It has been discussed that the ratio between the two peaks can be correlated to the surface area of the material [30]. In Figure 1 (e), the titanium atom shows two distinct peaks at 458.4 eV for the Ti2p_{1/2} and at 459.2 eV for the Ti2p_{3/2} showing the clear evidence of the element present in the surface of the Ppy-CS-TiO₂ nanocomposite films [31].

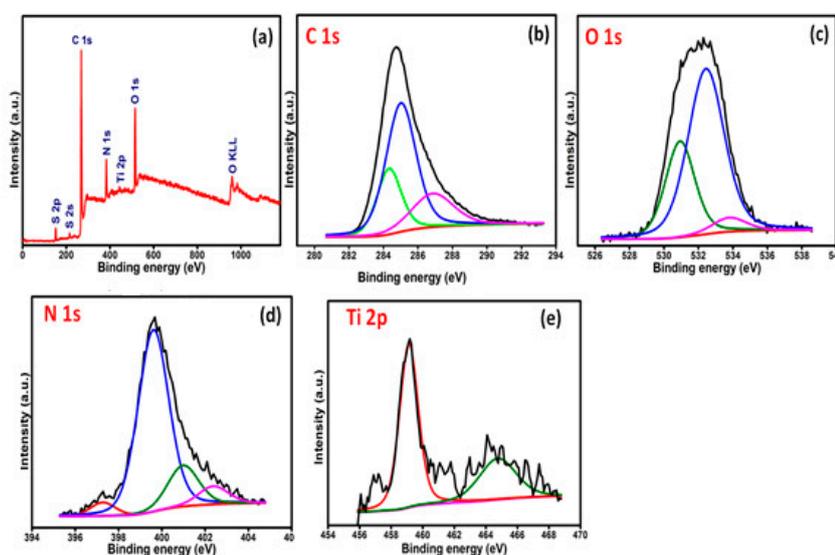

Figure 1. The XPS survey scan (a) and narrow scan (b, c, d, and e) of Ppy-CS-TiO₂ nanocomposite films.

dynamic range of 1 to 14 mM with a correlation coefficient of 0.989, a sensitivity of $0.008 \mu\text{Acm}^{-2} \text{mM}^{-1}$, and low detection limit (LOD) of $614 \mu\text{M}$ of ($S/N=3$). This novel Ppy-CS-TiO₂ nanocomposite /ITO glucose sensor exhibits good sensitivity, low detection limit and fast response time in less than 3 seconds. TiO₂ nanoparticles in PPy-CS-TiO₂ is showing much higher current response compared to the electrode (PPy-CS) without TiO₂ as can be seen in Figure 3 (b) for the amperometric responses to the successive addition of glucose.

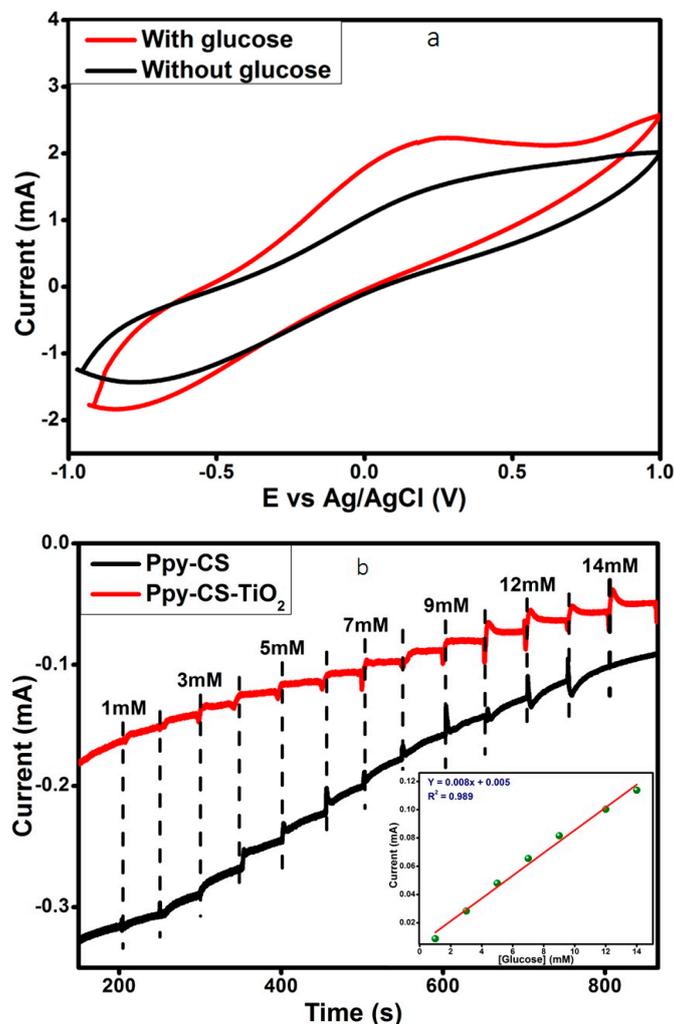

Figure 3. (a) CV responses of Ppy-CS-TiO₂ /ITO in 0.1M NaOH electrolyte with 1mM glucose and without glucose at the scan rate of 50 mVs^{-1} . (b) Amperometric responses to successive addition of glucose concentration in 0.1M NaOH solution at $+0.13 \text{ V}$ (vs. Ag/AgCl). The inset shows the steady-state calibration curve for the of Ppy-CS-TiO₂ nanocomposite /ITO electrode.

Figure 4 (a) describes the comparison of cyclic voltammetric responses obtained at the bare ITO, Ppy-CS composite and Ppy-CS-TiO₂ nanocomposites for $1 \text{ mM K}_3[\text{Fe}(\text{CN})_6]$ in 0.1 M KCl at a scan rate of 50 mV s^{-1} . The bare ITO electrode shows a reversible voltammetric characteristic for the one electron redox process of $[\text{Fe}(\text{CN})_6]^{3-/4-}$ at a scan rate of 50 mV s^{-1} . The Ppy-CS composite and Ppy-CS-TiO₂ nanocomposite electrodes show in Figure 4 (a) enhanced redox peak currents with a peak to peak separation, when compared to bare ITO. The high conductivity of Ppy facilitated the electron transfer and presented a higher peak current of oxidation and reduction peaks values ($480 \mu\text{A}$ and $-500 \mu\text{A}$) for the Ppy-CS composite electrode and likewise for the nanocomposite electrode ($580 \mu\text{A}$ and $-580 \mu\text{A}$). It was found that the nanocomposites containing TiO₂ increase the electrocatalytic activity and appears as a good electrical communicator with the original electrode surface. It was noticeably found that the nanocomposite electrode performs as a new electrode surface; this is due

to the effect of both TiO₂ and Ppy which increased the electrocatalytic activity and appeared as a good electrical communicator with the original electrode surface.

The interfacial properties of nanocomposite electrodes were studied by electrochemical impedance spectroscopy (EIS) in Figure 4 (b). The Nyquist diagram of the complex impedance shows that the bare ITO electrode has a semicircle-like shape Nyquist plot with a large diameter which recommends the hindrance to the electron-transfer kinetics at the electrode. For Ppy-CS-TiO₂ nanocomposites, no semi-circle was observed which shows the higher electron transfer kinetics. Additionally, the composite and nanocomposite electrodes presented only the linear portion at lower frequencies. This semicircle compared to the other electrodes, which is a result of the large charge-transfer resistance (R_{ct}) at the electrode/electrolyte interface due to the poor electron transfer kinetics. It can obviously be seen that (R_{ct}) decreased for the Ppy-CS composite and Ppy-CS-TiO₂ nanocomposite electrodes, which can be attributed to the presence of high conductive Ppy and catalytically active TiO₂ nanoparticles on the electrode surface. The diffusion-limited process was much more facilitated at the nanocomposite electrodes owing to the conducting properties of Ppy and the large surface area of TiO₂ in the nanocomposites.

The conducting nature of Ppy in both the composite and nanocomposite electrode facilitates the peak shifting in the Bode plot showed in Figure 4 (c). The Bode impedance plot of the nanocomposite electrode presented a lesser log Z value in a low frequency range of 1–100 Hz when compared to the composite electrodes.

In Figure 4 (d), the Bode-phase plots of the nanocomposite electrodes were collected in the frequency range of 0.01–10000 Hz. The phase peaks appeared at a frequency range of 100–10000 Hz which corresponds to the charge-transfer resistance of the nanocomposite electrodes. The shifting of peaks toward the low frequency region of 1–0.01 Hz for composite and nanocomposite electrodes indicates the fast electron-transfer behaviour of the nanocomposites. A perfect linear portion was observed at lower frequencies for the nanocomposite electrode compared to the other electrodes. These results indicate that the Ppy-CS-TiO₂ nanocomposite was successfully designed and it facilitated a diffusion-limited process at the electrode-solution interface.

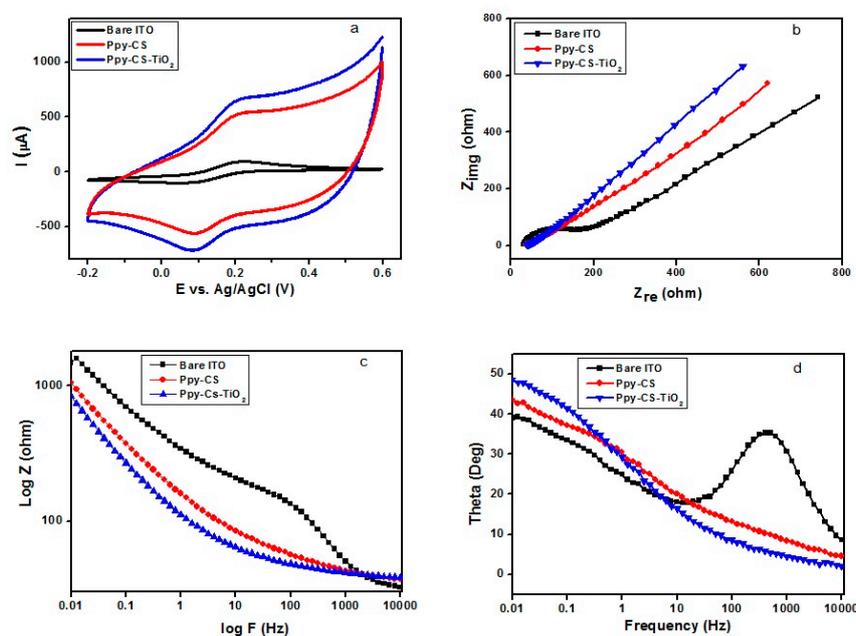

Figure 4. (a) Cyclic voltammograms obtained for bare ITO, Ppy-CS composite and Ppy-CS-TiO₂ nanocomposites (b) Nyquist plots, (c) Bode impedance phase plots of log z, (d) Bode phase plots, for 1 mM K₃[Fe(CN)₆] in 0.1 MKCl at a scan rate of 50 mVs⁻¹ vs (Ag/AgCl).

The stability of the developed sensor was investigated by measuring its current response for glucose for 14 days. The prepared Ppy-CS-TiO₂ nanocomposite films on ITO was used to record the amperometric response for 1mM glucose with a frequency of 2 days. Figure 5 represented stability of Ppy-CS-TiO₂/ ITO modified electrode over 14 days. I_0 is the current response of fresh sensor and I_{14} is the current response after 14days storage as shown in Figure 5. During the first 6 days, the current response did not change in a noticeable way. However, on the 14th day (last day), the current response still remained above 88 % of its initial response, revealing the excellent stability of the non-enzymatic glucose sensor.

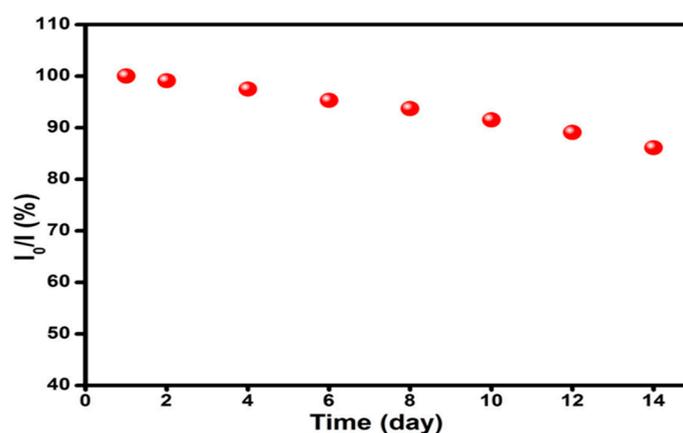

Figure 5. Stability of the sensor stored at ambient conditions over 14 days in 0.1 M NaOH glucose at potential of 0.13 V (vs. Ag/AgCl).

The selectivity of the Ppy-CS-TiO₂ nanocomposite /ITO for the detection of glucose was examined by injecting three different interfering biomolecules, namely, (UA), (AA) and (CH) in the evenly stirred 0.1 M NaOH solution containing glucose. Figure 6 depicts the recorded amperometric responses for the consecutive additions of glucose and the interfering biomolecules. First, the successive injections of glucose (each time, 1 mM) were used to record the current response for two injections after every 50 sec. The clear response towards detection was observed. No response was observed after that the consecutive injections of UA, AA and cholesterol (each time, 0.1 mM) in the same stirred solution. Later glucose was added by three injections (each time, 1 mM) and the current response was observed. It was found that, the addition of interfering biomolecules did not contribute significant changes on current response contrary to the glucose solution which represented a high response for each injection. These results revealed that the present sensor possesses a good selectivity and sensitivity towards the detection of glucose even in the presence of common physiological interfering biomolecules.

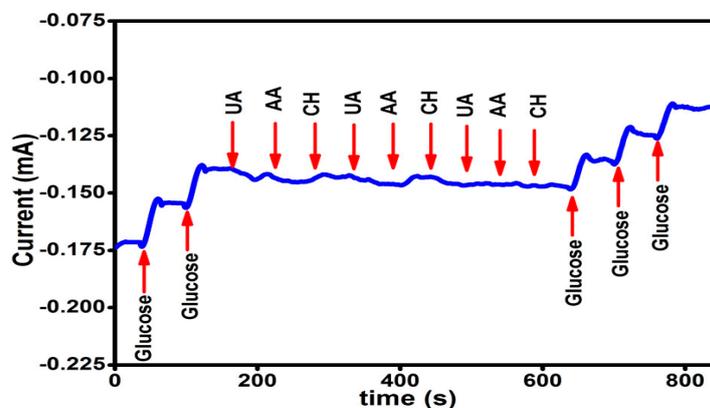

Figure 6. Amperometric responses obtained at successive addition of glucose and each of uric acid, ascorbic acid and cholesterol in 0.1 M NaOH solution at +0.13 V (vs. Ag/AgCl) with regular interval of 50 s.

3. Materials and Methods

Chitosan, was purchased from (ACROS Organics), New Jersey, USA. TiO_2 Np >20 nm, D (+) glucose sodium, para toluene sulfonate (*p*-TS), ascorbic acid (AA), uric acid (UA) and cholesterol (CH) were all purchased from Sigma–Aldrich. Acetic acid, sodium hydroxide and freshly distilled pyrrole 99% were provided by Merck. Indium tin oxide (ITO) glass electrode was purchased from (Fluka, Japan). A stock solution of D (+) glucose was prepared (1M) and left overnight for studying the sensing performance of the modified electrode. A stock solution of NaOH (0.1 M) was prepared using distilled water. A stock solution was prepared containing potassium ferricyanide (1×10^{-3}) M $\text{K}_3[\text{Fe}(\text{CN})_6]$ in potassium chloride (0.1) M KCl.

3.1 Instrument

Field emission scanning electron microscope (FESEM, Hitachi Brand, Model SU 8220) and high-resolution transmission electron microscope (HRTEM) (Tecnai model G2-F20)-Twin manufacture (FEI, USA) were used for the investigation of the morphology and structural properties of the deposited nanocomposite films. The presence of the nanoparticles in the prepared films was determined by X-ray photoelectron spectroscopy (XPS) brand (ULVAC-PHI Quantera II (Ulvac-PHI, INC). All electrochemical measurements were performed using a computerized potentiostat Instrument, made by Digi-ivy, Inc.(USA). A conventional three-electrode system comprising of an ITO glass electrode, graphite rode and Ag/AgCl were used as working electrode, counter electrode and reference electrode, respectively.

3.2 Preparation of Ppy-CS - TiO_2 NP/ ITO nanocomposite films

TiO_2 Np were dispersed into 25 mL of CS (50 mg/mL) solution under continuous stirring at room temperature followed by ultrasonication for 2 h to obtain a viscous solution of CS with uniformly dispersed TiO_2 Np. Later certain amount of pyrrole and *p*-TS as a dopant were added to the CS and TiO_2 dispersion and stirred for 5 min. The prepared dispersion of Ppy-CS- TiO_2 was used for the electrochemical deposition of the film on ITO glass electrode by cyclic voltammetry scanning ranging from -1V to +1.2 V (vs. Ag/AgCl) with a scan rate of 50 mV/s using the three-electrode system. The Ppy-CS- TiO_2 nanocomposite films were then washed repeatedly with distilled water to remove any unbound particles and later dried at room temperature. The prepared films were characterized and subjected to electrochemical oxidation of glucose.

3.3 Mechanism for the formation of Ppy-CS- TiO_2 on ITO

In this study, cyclic voltammetry was used for the electrochemical deposition of conducting polymer nanocomposite films on ITO glass electrode where all the components like the monomer, the dopant, chitosan, and the nanoparticle were dissolved in the solvent in the electrochemical cell as seen in Figure 7.

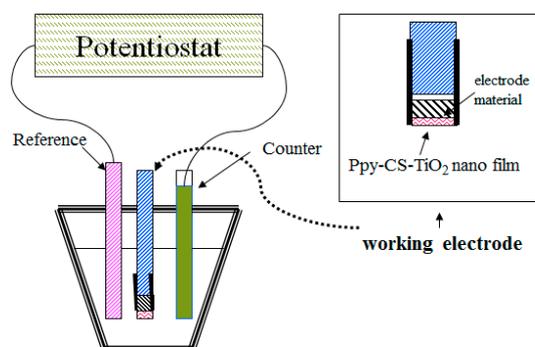

Figure 7. The electrochemical cell of Ppy- CS- TiO_2 film preparation

During this one-step, electrochemical formation of CS-PPy-TiO₂ nanocomposite films, polypyrrole is linked with CS-TiO₂ through hydrogen bonding and titanium-nitrogen ligand formation. The CS-TiO₂ are linked with hydrogen bonding during ultra-sonication in the preparatory stage as shown in Figure 8.

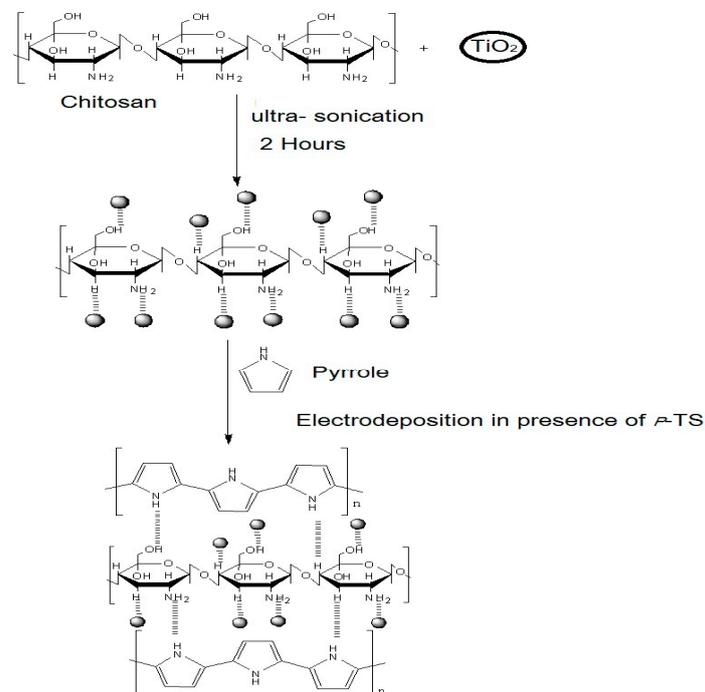

Figure 8. The mechanism of Ppy- CS-TiO₂ film electrodeposition.

4. Conclusions

We wish to report on the successful preparation of PPy-CS-TiO₂ nanocomposite films on ITO glass electrode as non-enzymatic glucose biosensors. The electrochemically prepared nanocomposite films (PPy-CS-TiO₂) exhibited an excellent electrocatalysis towards glucose oxidation in alkaline media. TiO₂ as a nanomaterial played a vital role in glucose oxidation together with polypyrrole and chitosan as has been observed in this study. The nanocomposite films showed a low detection limit, wide linear range, fast response time, high current for glucose oxidation with good stability. EIS study shows the lowest charge transfer resistance for the prepared (PPy-CS-TiO₂) nanocomposite films. As a glucose sensor, the prepared (PPy-CS-TiO₂) nanocomposite electrode is immune to other biomolecules such as uric acid, ascorbic acid and cholesterol. Considering the low-cost, facile and controllable method for the preparation of (PPy-CS-TiO₂) nanocomposite films and improved electrocatalytic activity toward glucose oxidation, the future of this non-enzymatic glucose sensor looks bright.
