SERIES REPRESENTATION OF POWER FUNCTION

KOLOSOV PETRO

ABSTRACT. In this paper we discuss a problem of generalization of binomial distributed triangle, that is sequence A287326 in OEIS. The main property of A287326 that it returns a perfect cube \( n \) as sum of \( n \)-th row terms over \( k \), such that \( 0 \leq k \leq n - 1 \) or \( 1 \leq k \leq n \), by means of its symmetry. In this paper we have derived a similar triangles in order to receive powers \( m = 5, 7 \) as row items sum and generalized obtained results in order to receive every odd-powered monomial \( n^{2m+1} \), \( m \geq 0 \) as sum of row terms of corresponding triangle. In other words, in this manuscript are found and discussed the polynomials \( D_m(n, k) \) and \( U_m(n, k) \), such that, when being summed up over \( k \) in some range with respect to \( m \) and \( n \) returns the monomial \( n^{2m+1} \).

1. Structure of the manuscript

The problem of finding expansions of monomials, binomials, trinomials, etc. is classical and a lot of theorems have been found, the most prominent examples are Binomial Theorem [2], Multinomial theorem, Worpitzky Identity [30], [34], Stirling numbers of second kind and falling factorial identity, [36], etc. In this paper we try to solve the classical problem of finding expansions of monomials. We start from binomial distributed triangle A287326 [11] in OEIS. The main property of A287326 that it returns a perfect cube \( n \) as \( n \)-th row sum, starting from 0, ..., \( n - 1 \) or from 1, ..., \( n \) by means of its symmetry. Therefore, the following question stated:

- Is there a generalization of A287326 in order to receive monomial \( n^t \), \( t > 3 \) as sum of \( n \)-th row terms of corresponding triangle, where \( t \) is natural?

Finding an analogs for \( t = 5, 7 \) in section 3 we answer to above questions positively. Could this process be continued for each odd \( t = 1, 3, 5, 7 \)... similarly? Positive answer to this question is given by [theorem (3.30)]

Date: August 17, 2018.

2. INTRODUCTION

Let describe the derivation of the sequence \[A287326\] in OEIS. Sequence \[A287326\] returns the perfect cube \(n\) as row sum over \(k\), \(0 \leq k \leq n - 1\), as well as sum over \(1 \leq k \leq n\), by means of its symmetry. First, consider a difference table of perfect cubes ([4], eq. 7)

\[
\begin{array}{c|c|c|c|c}
 n & \Delta^0(n^3) & \Delta^1(n^3) & \Delta^2(n^3) & \Delta^3(n^3) \\
 \hline
 0 & 0 & 1 & 6 & 6 \\
 1 & 1 & 7 & 12 & 6 \\
 2 & 8 & 19 & 18 & 6 \\
 3 & 27 & 37 & 24 & 6 \\
 4 & 64 & 61 & 30 & 6 \\
 5 & 125 & 91 & 36 & 6 \\
 6 & 216 & 127 & 42 & 6 \\
 7 & 343 & 169 & 48 & 6 \\
 8 & 512 & 217 & 54 & 6 \\
 9 & 729 & 271 & & \\
 10 & 1000 & & & \\
\end{array}
\]

Table 1: Difference table of perfect cubes \(n\), \(0 \leq n \leq 10\) up to 3\(^{rd}\) order.

Reviewing above table, we have noticed that

\[
\Delta(n^3) = 1 + 6 \cdot 0 + 6 \cdot 1 + \cdots + 6 \cdot n = 6(n+1) + \binom{n+1}{0}.
\]

Above difference identity is closely related to Faulhaber’s sum of cubes, where \(n^3 = 6\left(\frac{n+1}{3}\right) + \binom{n+1}{1}\), see ([21], p. 9). Note that \(\Delta^2(n^3)\) could be found similarly using above identity, i.e \(\Delta^2(n^3) = 6\left(\frac{n+1}{3}-2\right) + \binom{n+1}{1} \cdot \binom{n+1}{2-1}\).

Property 2.3. (Generalized finite difference of power using Faulhaber’s formula). Consider the identities, ([21], p. 9). For every odd power

\[
\begin{align*}
n^1 &= \binom{n}{1} \\
n^3 &= 6\left(\frac{n+1}{3}\right) + \binom{n}{1} \\
n^5 &= 120\left(\frac{n+2}{5}\right) + 30\left(\frac{n+1}{3}\right) + \binom{n}{1} \\
&\vdots \\
n^{2m-1} &= \sum_{1 \leq k \leq m} (2k-1)!T(2m, 2k)\left(\frac{n+k-1}{2k-1}\right)
\end{align*}
\]

The coefficients in these formulas are related to what Riordan [22] has called central factorial numbers of the second kind. In his notation,

\[
x^m = \sum_{1 \leq k \leq m} T(m, k)x^{[k]}, \quad x^{[k]} = x(x+\frac{k}{2}-1)(x+\frac{k}{2}-2)\cdots(x+\frac{k}{2}+1)
\]

The coefficients \(T(2m, 2k)\) are always integers, because the \(x^{[k+2]} = x^{[k]}(x^2/k^4)\) implies the recurrence

\[T(2m+2, 2k) = k^2T(2m, 2k) + T(2m, 2k-2)\].
We can find the first order finite difference of odd power as decreasing the variable of corresponding binomial coefficients by 1, for example

\[
\begin{align*}
\Delta n^1 &= \binom{n}{0} \\
\Delta n^3 &= 6\binom{n+1}{2} + \binom{n}{0} \\
\Delta n^5 &= 120\binom{n+2}{4} + 30\binom{n+1}{2} + \binom{n}{0} \\
\vdots \\
\Delta n^{2m-1} &= \sum_{1 \leq k \leq m} (2k-1)!T(2m, 2k)\binom{n+k-1}{2k-2}
\end{align*}
\]

Continue similarly, we can express each difference of order \(t \geq 1\). The central factorial numbers of the second kind \((2k-1)!T(2m, 2k)\) in above identities are terms of OEIS sequence [A303675] and generated by

\[
(2.4) \quad (2k-1)!T(2m, 2k) = \frac{1}{r} \sum_{j=0}^{r} (-1)^{j}\binom{2r}{j}(r-j)^{2n} =: V_{m,k},
\]

where \(r = n-k+1\), this formula was provided by Peter Luschny in [27]. Repeated sums are equally easy, in Knuth’s notation (see [21], p. 10)

\[
\Sigma r^{2m+1} = \sum_{1 \leq k \leq m} V_{m,k}\binom{n+k+r}{2k-1+r}
\]

Therefore, reviewing the difference as inverse operator to summation for every odd \(t > 0\) and \(m \geq 0\), we have identity

\[
\Delta^t n^{2m+1} = \sum_{1 \leq k \leq m} V_{m,k}\binom{n+k-r}{2k-1-r}
\]

\[\square\]

By property [2.3] we rewrite the cubes as

\[
(2.5) \quad n^3 = \sum_{1 \leq k \leq n} 6\binom{k+1}{2} + \binom{k}{0}
\]

Rewrite above expression with set every binomial coefficient to be \(\binom{n+1}{2} = 1 + 2 + \cdots + (n+1)\), then

\[
n^3 = (1 + 6 \cdot 0) + (1 + 6 \cdot 0 + 6 \cdot 1) + \cdots + (1 + 6 \cdot 0 + \cdots + 6 \cdot (n-1))
\]

Particularizing above expression, we get

\[
(2.6) \quad n^3 = n + (n-0) \cdot 6 \cdot 0 + (n-1) \cdot 6 \cdot 1 + \cdots + (n-(n-1)) \cdot 6 \cdot (n-1)
\]

Provided that \(n\) is natural. Now, let apply a compact sigma notation on (2.6), thus

\[
(2.7) \quad n^3 = n + \sum_{1 \leq k \leq n} 6k(n-k)
\]

As sum \(\sum_{1 \leq k \leq n} 6k(n-k)\) consists of \(n\) terms, we have right to move \(n\) in (2.7) under sigma notation, we get

\[
(2.8) \quad n^3 = \sum_{1 \leq k \leq n} 6k(n-k) + 1
\]

**Property 2.9. (Proof of symmetry).** Let be a sets \(A(n) := \{1, 2, \ldots, n\}\), \(B(n) := \{0, 1, \ldots, n\}\), \(C(n) := \{0, 1, \ldots, n-1\}\), let be expression (2.8) denoted as

\[
M(n, C(n)) = \sum_{k \in C(n)} 6k(n-k) + 1
\]
where $n$ is natural-valued variable and $C(n)$ is iteration set of (2.8), then we have equality

(2.10) \[ M(n, A(n)) = M(n, C(n)) \]

Let review and denote expression (2.6) as

\[ U(n, C(n)) = n + 6 \cdot \sum_{k \in C(n)} k(n - k) \]

then

(2.11) \[ U(n, A(n)) = U(n, B(n)) = U(n, C(n)) \]

Other words, changing of iteration sets of (2.6) and (2.8) by $A(n)$, $B(n)$, $C(n)$ and $A(n)$, $C(n)$, respectively, doesn’t change resulting value for each natural $x$.

Proof. Let be a plot $y(n, k) = 6k(n - k) + 1$, $k \in \mathbb{R}$, $0 \leq k \leq n$, given $n = 10$

Figure 2. Plot of $6k(n - k) + 1$, $k \in \mathbb{R}$, $0 \leq k \leq n$, where $n = 10$.

Obviously, being a parabolic function, it’s symmetrical over $\frac{n}{2}$, hence equivalent $M(n, A(n)) = M(n, C(n))$ follows. Reviewing (2.6) and denote $u(n, k) = kn - k^2$, we can conclude, that $u(n, 0) = u(n, n) = 0$, then equality of $U(n, A(n)) = U(n, B(n)) = U(n, C(n))$ immediately follows. This completes the proof. \[\square\]

Review above property (2.9). Let be an example of triangle built using

Definition 2.12. For every $n \geq 0$

(2.13) \[ D_1(n, k) \overset{\text{def}}{=} 6k(n - k) + 1, \ 0 \leq k \leq n \]

over $n$ from 0 to $n = 4$, where $n$ denotes corresponding row and $k$ shows the item of row $n$.

Row 0: \[
\begin{array}{c}
1
\end{array}
\]

Row 1: \[
\begin{array}{cc}
1 & 1
\end{array}
\]

Row 2: \[
\begin{array}{ccc}
1 & 7 & 1
\end{array}
\]

Row 3: \[
\begin{array}{cccc}
1 & 13 & 13 & 1
\end{array}
\]

Row 4: \[
\begin{array}{ccccc}
1 & 19 & 25 & 19 & 1
\end{array}
\]

Figure 3. Triangle generated by $D_1(n, k)$, sequence [A287326] in OEIS. [11].
SERIES REPRESENTATION OF POWER FUNCTION

Note that \( n \)-th row sum of Triangle \((2.14)\) over \( 0 \leq k \leq n - 1 \) returns perfect cube \( n \). We can see that each row with respect to variable \( n = 0, 1, 2, 3, 4, \ldots \), has Binomial distribution of row terms. One could compare Triangle \((2.14)\) with Pascal’s triangle \([1], [12]\)

<table>
<thead>
<tr>
<th>Row 0:</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row 1:</td>

</tr>
<tr>
<td>Row 4:</td>
<td>1 4 6 4 1</td>
</tr>
</tbody>
</table>

Figure 4. Pascal’s triangle, sequence A007318 in OEIS, \([1]\).

Let us approach to show a few properties of triangle \((2.14)\) and \( L_1(n, k) \).

Properties 2.15. Properties of triangle \((2.14)\).

1. Summation of \( n \)-th row of triangle \((2.14)\) over \( k \) from 0 to \( n - 1 \) returns perfect cube \( n \geq 0 \) as follows

\[
 n^3 = \sum_{1 \leq k \leq n} D_1(n, k)
\]

(2.16)

2. First item of each row’s number corresponding to central polygonal numbers sequence \( a(n) = \frac{n^2 + n + 2}{2} \) (sequence A000124 in OEIS \([13]\)) returns finite difference of consequent perfect cubes. For example, let be a \( k \)-th row of triangle \((2.14)\), such that \( k = \frac{n^2 + n + 2}{2} \), \( n = 0, 1, 2, \ldots \), then item

\[
 \Delta(n^3) = D_1 \left( \frac{n^2 + n + 2}{2}, 1 \right)
\]

(2.17)

3. Items of \((2.14)\) have Binomial distribution of rows.

4. Linear recurrence, for every \( k \) and \( n > 0 \)

\[
 2D_1(n, k) = D_1(n + 1, k) + D_1(n - 1, k)
\]

This linear recurrence is direct result of second order binomial transform of \( D_1(n, k) \) by \( n \).

5. Linear recurrence, for each \( n > k \)

\[
 2D_1(n, k) = D_1(2n - k, k) + D_1(2n - k, 0)
\]

(2.19)

6. From \((1.24)\) for every \( n \geq 0 \) follows

\[
 n^3 = \sum_{1 \leq k \leq n} D_1(n, k) = \sum_{1 \leq k \leq n} D_1 \left( \frac{k^2 + k + 2}{2}, 1 \right)
\]

(2.20)

7. Triangle \((2.14)\) is symmetric, i.e

\[
 D_1(n, k) = D_1(n, n - k)
\]

Corollary 2.22. Review identity \((2.16)\) in sense of summation of \( D_1(n, k) \) over some range \( W \) with \( \max(W) = T \), then \((2.16)\) returns

\[
 \sum_{1 \leq k \leq T} D_1(n, k) = U_1(T, 0)n^0 - U_1(T, 1)n^1,
\]

where \( T = 1, 2, 3, \ldots, N \). By property \((2.9)\) we rewrite above expression as

\[
 \sum_{0 \leq k \leq T-1} D_1(n, k) = U_1(T - 1, 0)n^0 - U_1(T - 1, 1)n^1
\]

Below we show a few initial terms of \( U_1(T - 1, j), U_1(T, j), j = 0, 1 \) coefficients
Table 5. Table of coefficients $U_1(T-1,0), U_1(T-1,1), U_1(T,0), U_1(T,1)$ given $T = 1, ..., 10$.

Therefore, for every integer $n \geq 1$, $T = n$,

$$\forall T = n : \ n^3 = \begin{cases} 
U_1(T,0)n^0 - U_1(T,1)n^1, \\
U_1(T-1,0)n^0 - U_1(T-1,1)n^1.
\end{cases}$$

Coefficients $|U_1(T-1,1)|$ are terms of sequence A028896 in OEIS, [23]. Coefficients $|U_1(T,0)|$ are terms of sequence A275709 in OEIS, [20].

In this section we have derived a binomial distributed triangle (2.14), such that perfect cube $n^3$ could be found as sum of $n$-th row terms of triangle (2.14) over $k$, in ranges $1 \leq k \leq n$ or $0 \leq k \leq n-1$, where $n$ is natural. Therefore, the follow question is stated:

**Question 2.23.** Is there a generalization of A287326 in order to receive monomial $n^t$, $t > 3$ as sum of $n$-th row terms of corresponding triangle, where $t$ is natural?

### 3. Generalization of sequence A287326

In order to get analogs of Triangle (2.14) one should solve a system of equations, where unknowns are coefficients of polynomial and variable of polynomial is $k(n-k)$. Triangle (2.14) is generated by polynomial $D_1(n,k)$, $n \geq 0$, $0 \leq k \leq n$, defined by (2.12). Here, let derive a triangle generated by polynomial $D_2(n,k)$, $n \geq 0$, $0 \leq k \leq n$, such that sum of $n$-th row terms over $k$, in ranges $1 \leq k \leq n$ or $0 \leq k \leq n-1$ returns $n^5$, where $n$ is natural.

**Example 3.1.** We suspect that $n$-th row of triangle that returns $n^5$ as sum of $n$-th row terms over $k$, in $1 \leq k \leq n$ or $0 \leq k \leq n-1$ is generated by

$$D_2(n,k) = A_{2,2}(n-k)^2k^2 + A_{2,1}(n-k)^1k^1 + A_{2,0}(n-k)^0k^0, \ n \geq 0, \ 0 \leq k \leq n,$$

where $A_{2,2}, A_{2,1}, A_{2,0}$ are unknown coefficients. Assume that for every integer $n \geq 0$ holds

$$n^5 = \sum_{1 \leq k \leq n} D_2(n,k).$$

</tbody>
</table>
To determine the coefficients $A_{2,2}, A_{2,1}, A_{2,0}$, in (3.2) let rewrite (3.3) in extended view

$$A_{2,2} \sum_{1 \leq k \leq n} k^2(n - k)^2 + A_{2,1} \sum_{1 \leq k \leq n} k(n - k) + \sum_{1 \leq k \leq n} A_{2,0}$$

$$= A_{2,2} \sum_{1 \leq k \leq n} k^2(n^2 - 2nk + k^2) + A_{2,1} \sum_{1 \leq k \leq n} kn - k^2 + \sum_{1 \leq k \leq n} A_{2,0}$$

$$= A_{2,2} \sum_{1 \leq k \leq n} k^2n^2 - 2nk^3 + k^4 + A_{2,1} \sum_{1 \leq k \leq n} kn - k^2 + \sum_{1 \leq k \leq n} A_{2,0}$$

$$= A_{2,2}n^2 \sum_{1 \leq k \leq n} k^2 - 2A_{2,2}n \sum_{1 \leq k \leq n} k^3 + A_{2,2} \sum_{1 \leq k \leq n} k^4 + A_{2,1}n \sum_{1 \leq k \leq n} k$$

$$- A_{2,1} \sum_{1 \leq k \leq n} k^2 + \sum_{1 \leq k \leq n} A_{2,0} = n^5.$$

Thus, we have received expression containing sums of powers of successive natural numbers, where powers are $\{1, 2, 3, 4\}$. These formulas contain so-called Bernoulli numbers, [14]. For mentioned powers of successive natural numbers formulas are following

$$\sum_{1 \leq k \leq n} k = \frac{n^2 + n}{2},$$

$$\sum_{1 \leq k \leq n} k^2 = \frac{2n^3 + 3n^2 + n}{6},$$

$$\sum_{1 \leq k \leq n} k^3 = \frac{n^4 + 2n^3 + n^2}{4},$$

$$\sum_{1 \leq k \leq n} k^4 = \frac{6n^5 + 15n^4 + 10n^3 - n}{30}.$$

Now we substitute above identities to (3.4), respectively,

$$A_{2,2}n^2 \frac{2n^3 + 3n^2 + n}{6} - 2A_{2,2}n \frac{n^4 + 2n^3 + n^2}{4} + A_{2,2} \frac{6n^5 + 15n^4 + 10n^3 - n}{30}$$

$$+ A_{2,1}n \frac{n^2 + n}{2} - A_{2,1} \frac{2n^3 + 3n^2 + n}{6} + A_{2,0}n$$

Particularizing the elements of above expression and moving them under the common divisor, we get

$$\frac{A_{2,2}n^5 - A_{2,2}n + 30A_{2,0}}{30} + A_{2,1} \frac{n^3 - n}{6}$$

We have to remember that expression (3.9) is the left side of the input equation (3.3). Therefore,

$$n^5 = \frac{A_{2,2}n^5 - A_{2,2}n + 30A_{2,0}}{30} + A_{2,1} \frac{n^3 - n}{6}$$

In order to satisfy (3.10) for each natural $n$, coefficients $A_{2,0}, A_{2,1}, A_{2,2}$ should be a solutions of following system of equations

$$\begin{align*}
1 &= \frac{1}{30} A_{2,2} \\
1 &= A_{2,1} \\
0 &= 30A_{2,0} - A_{2,2}
\end{align*}$$
The only solution of above system is $A_{2,2} = 30$, $A_{2,1} = 0$, $A_{2,0} = 1$. Hereby, polynomial $D_2(n, k)$ takes the form

$$D_2(n, k) = A_{2,2}(n-k)^2k^2 + A_{2,1}(n-k)^1k^1 + A_{2,0}(n-k)^0k^0 = 30k^2(n-k)^2 + 1$$

And for every natural $n \geq 1$ holds

$$n^5 = \sum_{1 \leq k \leq n} D_2(n, k) = \sum_{1 \leq k \leq n} 30k^2(n-k)^2 + 1$$

Let show few initial rows of triangle built by $D_2(n, k)$, that is analog of triangle (2.14), which returns monomial $n^5$ as sum of $n$-th row terms over $k$, as $1 \leq k \leq n$ or $0 \leq k \leq n-1$, by means of its symmetry

Figure 6. Triangle generated by polynomial $D_2(n, k)$, $n \geq 0$, $0 \leq k \leq n$, sequence A300656 in OEIS.

Similarly, finding the coefficients $A_{3,0}$, $A_{3,1}$, $A_{3,2}$, $A_{3,3}$ in

$$D_3(n, k) = A_{3,3}k^3(n-k)^3 + A_{3,2}k^2(n-k)^2 + A_{3,1}k^1(n-k)^1 + A_{3,0}k^0(n-k)^0,$$

we get $A_{3,3} = 140$, $A_{3,2} = -14$, $A_{3,1} = 0$, $A_{3,0} = 1$, therefore, for each integer $n \geq 0$ holds

$$n^7 = \sum_{1 \leq k \leq n} D_3(n, k) = \sum_{1 \leq k \leq n} 140k^3(n-k)^3 - 14k^2(n-k)^2 + 1$$

Below we show a few initial rows of triangle generated by polynomial $D_3(n, k)$, $n \geq 0$, $0 \leq k \leq n$, the analog of triangle (2.14), such that monomial $n^7$ could be found as sum of $n$-th row terms over $k$, as $1 \leq k \leq n$ or $0 \leq k \leq n-1$, by means of its symmetry

Figure 7. Triangle generated by polynomial $D_3(n, k)$, $n \geq 0$, $0 \leq k \leq n$, sequence A300785 in OEIS.
We assume now that generalization of $A287326$ holds for odd powers of the form $2m + 1$, $m = 0, 1, 2, \ldots$, where $A287326$ is partial case for $m = 1$. To generalize our sequences $A287326$ $A300656$, $A300785$ for every odd power $2m + 1$, $m \geq 0$ one has to review the generating functions of sequences $A287326$ $A300656$ $A300785$ as follows. Let be definition

**Definition 3.17.**

\[
D_m(n, k) := A_{m,m} k^m (n - k)^m + A_{m,m-1} k^{m-1} (n - k)^{m-1} + \cdots + A_{m,0} k^0 (n - k)^0
\]

\[
= \sum_{0 \leq j \leq m} A_{m,j} k^j (n - k)^j,
\]

where $A_{m,j}$, $0 \leq j \leq m$ are unknown coefficients.

And, we assume that

\[
n^{2m+1} = \sum_{1 \leq k \leq n} D_m(n, k).
\]

We want to notice that as we used a compact sigma notation on definition (3.17), i.e. we rewrite (3.17) as $\sum_{0 \leq j \leq m} A_{m,j} k^j (n - k)^j$, thus the sum (3.18) returns indeterminate form of $D_m(n, k) = \sum_{0 \leq j \leq m} A_{m,j} k^j (n - k)^j$ on step $k = n$ as $A_{m,0} (n - n)^0 k^0$ contains the term $(n - n)^0 = 0$. Some textbooks leave the quantity $0^0$ undefined, because the functions $x^0$ and $0^x$ have different limiting values when $x$ decreases to 0. But this is a mistake. We must define

\[
\forall x: x^0 = 1,
\]

if the binomial theorem is to be valid when $x = 0, y = 0$, and/or $x = y$. The binomial theorem is too important to be arbitrarily restricted! By contrast, the function $0^x$ is quite unimportant, [M]. Note that $D_m(n, k)$ is generalization of (2.12) and (3.11). For example, generating functions of sequences $A287326$ $A300656$ $A300785$ are, respectively

\[
\begin{align*}
D_1(n, k) &= 1 + 6k(n - k), &\text{for } A287326 \\
D_2(n, k) &= 1 - 6k(n - k) + 30k^2(n - k)^2, &\text{for } A300656 \\
D_3(n, k) &= 1 - 14k(n - k) + 6k^2(n - k)^2 + 140k^3(n - k)^3, &\text{for } A300785
\end{align*}
\]

Where coefficients $A_{m,j}$, for $m = 1, 2, 3$ are $\{A_{1,j}\}_{j=0}^1 = \{1, 6\}$, $\{A_{2,j}\}_{j=0}^2 = \{1, 0, 30\}$, $\{A_{3,j}\}_{j=0}^3 = \{1, -14, 0, 140\}$ in definitions of generating functions of $A287326$ $A300656$ $A300785$. To generalize above result in order to receive monomial $n^{2m+1}$ as $\sum_{1 \leq k \leq n} D_m(n, k) = n^{2m+1}$, $m = 0, 1, 2, \ldots$ one has to solve the system of equations. Complete set of coefficients $\{A_{m,0}, \ldots, A_{m,m}\}$ such that $\sum_{1 \leq k \leq n} D_m(n, k) = n^{2m+1}$, $m \geq 0$ holds can be found by solving the following system of equations

\[
\begin{align*}
D_m(1, 0) &= 1^{2m+1} \\
D_m(2, 0) + D_m(2, 1) &= 2^{2m+1} \\
D_m(3, 0) + D_m(3, 1) + D_m(3, 2) &= 3^{2m+1} \\
&\vdots \\
D_m(r, 0) + D_m(r, 1) + \cdots + D_m(r, r - 1) &= r^{2m+1}, &r > m
\end{align*}
\]

List of solutions of system (3.19) is split and assigned to OEIS under the numbers $A302971$ (numerator of $A_{m,j}$) and $A304042$ (denominator of $A_{m,j}$). To reach recurrent formula of $A_{m,j}$,
first let fix the unused values $A_{m,j} = 0$, for $j < 0$ or $j > m$, so we don’t need to care about the summation range for $j$, then by expanding $(n-k)^j$ and using Faulhaber’s formula [7], we get

\begin{equation}
\sum_{k=0}^{n-1} (n-k)^j k^j = \sum_{k=0}^{n-1} \sum_{i} (\begin{array}{c} j \\ i \end{array}) n^{j-i} (-1)^i k^{i+j}
\end{equation}

\begin{align*}
&= \sum_{i} \left( \begin{array}{c} j \\ i \end{array} \right) n^{j-i} \left[ \sum_{t} \left( \begin{array}{c} i+j+1 \\ t \end{array} \right) B_{t} n^{i+j+1-t} - B_{i+j+1} \right] \\
&= \sum_{i,t} \left( \begin{array}{c} j \\ i \end{array} \right) \frac{(-1)^i}{i+j+1} \left( \begin{array}{c} i+j+1 \\ t \end{array} \right) B_{t} n^{2j+1-t} - \sum_{i} \left( \begin{array}{c} j \\ i \end{array} \right) \frac{(-1)^i}{i+j+1} B_{i+j+1} n^{j-i}
\end{align*}

where $B_t$ are Bernoulli numbers [13]. Now, we notice that

\begin{equation}
\sum_{t} \left( \begin{array}{c} j \\ i \end{array} \right) \frac{(-1)^i}{i+j+1} \left( \begin{array}{c} i+j+1 \\ t \end{array} \right) = \begin{cases} \frac{1}{(2j+1)(\begin{array}{c} 2j \\ t \end{array})}, & \text{if } t = 0; \\
\frac{(-1)^j}{t \left( \begin{array}{c} j \\ 2j-t+1 \end{array} \right)}, & \text{if } t > 0 
\end{cases}
\end{equation}

In particular, the last sum is zero for $0 < t \leq j$. Now we revise the $(\star)$ part of (3.20) according to results of (3.21), thus

\begin{align*}
\sum_{i,t} \left( \begin{array}{c} j \\ i \end{array} \right) \frac{(-1)^i}{i+j+1} \left( \begin{array}{c} i+j+1 \\ t \end{array} \right) B_{t} n^{2j+1-t} &= \frac{1}{(2j+1)(\begin{array}{c} 2j \\ t \end{array})} \\
&+ \sum_{t>0} \frac{(-1)^j}{t \left( \begin{array}{c} j \\ 2j-t+1 \end{array} \right)} B_{t} n^{2j+1-t}
\end{align*}

Therefore, (3.20) takes the form

\begin{equation}
\sum_{k=0}^{n-1} (n-k)^j k^j = \frac{1}{(2j+1)(\begin{array}{c} 2j \\ j \end{array})} + \sum_{t>0} \frac{(-1)^j}{t \left( \begin{array}{c} j \\ 2j-t+1 \end{array} \right)} B_{t} n^{2j+1-t}
\end{equation}

\begin{align*}
&- \sum_{i} \left( \begin{array}{c} j \\ i \end{array} \right) \frac{(-1)^i}{i+j+1} B_{i+j+1} n^{j-i}
\end{align*}

Now, we keep our attention to (3.22) and we have to remember that if the sum over some variable $i$ contains $(\begin{array}{c} i \\ j \end{array})$, then instead of limiting its summation range to $i = 0, \ldots, j$, we can let $i = -\infty, \ldots, +\infty$ since $(\begin{array}{c} i \\ j \end{array}) = 0$ for $i$ outside the range $i = 0, \ldots, j$ (i.e., when $i < 0$ or $i > j$). It’s much easier to review such sum as summing from $-\infty$ to $+\infty$ (unless specified otherwise), where only a finite number of terms are nonzero, this fact is discussed in [28] as well. To combine or cancel identical terms across the two sums in (3.22) more easily, we introduce $\ell = 2j+1-t$ to $(\star)$ and $\ell = j-i$ to $(\odot)$,
respectively, we get

\begin{equation}
\sum_{k=0}^{n-1} (n-k)k^j = \frac{1}{(2j+1)}(2j)_j \, n^{2j+1} + \sum_{\ell=-\infty}^{\infty} \frac{(-1)^j}{2j+1-\ell} \binom{j}{\ell} B_{2j+1-\ell} n^\ell
\end{equation}

\begin{equation}
- \sum_{\ell=-\infty}^{\infty} \frac{(-1)^{j-\ell}}{2j+1-\ell} B_{2j+1-\ell} n^\ell
\end{equation}

\begin{equation}
= \frac{1}{(2j+1)}(2j)_j \, n^{2j+1} + 2 \sum_{\ell=0}^{\infty} \frac{(-1)^j}{2j+1-\ell} \binom{j}{\ell} B_{2j+1-\ell} n^\ell.
\end{equation}

Now, using the definition of $A_{m,j}$, we obtain the following identity for polynomials in $n$

\begin{equation}
\sum_{j} A_{m,j} \frac{1}{(2j+1)(2j)_j} n^{2j+1} + 2 \sum_{j, \text{ odd } \ell} A_{m,j} \binom{j}{\ell} \frac{(-1)^j}{2j+1-\ell} B_{2j+1-\ell} n^\ell \equiv n^{2m+1}.
\end{equation}

Taking the coefficient of $n^{2m+1}$ in above expression, we get $A_{m,m} = (2m+1)(2m)_m$, and taking the coefficient of $x^{2d+1}$ for an integer $d$ in the range $m/2 \leq d < m$ we get $A_{m,d} = 0$. Taking the coefficient of $n^{2d+1}$ in (3.24) for $m/4 \leq d < m/2$ , we get

\begin{equation}
A_{m,d} \frac{1}{(2d+1)(2d)_d} + 2(2m+1) \binom{2m}{m} \binom{m}{2d+1} \frac{(-1)^m}{2m-2d} B_{2m-2d} = 0,
\end{equation}

i.e.

\begin{equation}
A_{m,d} = (-1)^{m-1} \frac{(2m+1)!}{d!d!(m-2d-1)!} \frac{1}{m-d} B_{2m-2d}.
\end{equation}

Continue similarly, we can express $A_{m,j}$ for each integer $j$ in range $m/2^{s+1} \leq j < m/2^s$ (iterating consecutively $s = 1, 2, \ldots$) via previously determined values of $A_{m,d}, d < j$ as follows

\begin{equation}
A_{m,j} = (2j+1) \binom{2j}{j} \sum_{d=2j+1}^{m} A_{m,d} \binom{d}{2j+1} \frac{(-1)^{d-1}}{d-j} B_{2d-2j}.
\end{equation}

The same formula holds also for $m = 0$. Note that in above sum $m$ have to be $m \geq 2j+1$ to return nonzero term $A_{m,j}$.

**Definition 3.28.** We define here a generating function of sequence of coefficients $A_{m,j}$, such that $\sum_{k=0}^{n-1} D_m(n,k) = n^{2m+1}$, $n > 0$, $m > 0$, where $D_m(n,k)$ is defined by (3.17)

\[ A_{m,j} := \begin{cases} 
0, & \text{if } j < 0 \text{ or } j > m \\
(2j+1)(2j)_j \sum_{d=2j+1}^{m} A_{m,d} \binom{d}{2j+1} \frac{(-1)^{d-1}}{d-j} B_{2d-2j}, & \text{if } 0 \leq j < m \\
(2j+1)(2j)_j, & \text{if } j = m
\end{cases} \]

Five initial rows of triangle generated by $A_{m,j}$, $j \geq 0$, $0 \leq j \leq m$ are

\begin{align*}
m = 0 & \quad 1 \\
m = 1 & \quad 1 \quad 6 \\
m = 2 & \quad 1 \quad 0 \quad 30 \\
m = 3 & \quad 1 \quad -14 \quad 0 \quad 140 \\
m = 4 & \quad 1 \quad -120 \quad 0 \quad 0 \quad 630 \\
m = 5 & \quad 1 \quad -1386 \quad 660 \quad 0 \quad 0 \quad 2772
\end{align*}
Figure 8. Triangle generated by $A_{m,j}$, $j \geq 0$, $0 \leq j \leq m$, sequences $A302971$ (numerators of $A_{m,j}$) and $A304042$ (denominators of $A_{m,j}$).

Note that starting from row $m \geq 11$ the terms of Triangle (3.29) consist fractional numbers, for example, $A_{11,1} = 80036165623, 6$. One can find complete list of the numerators and denominators of $A_{m,j}$ in OEIS under the identifiers $A302971$ and $A304042$ respectively, see [17], [18]. To verify the terms that definition (3.28) produces one should refer to Mathematica code\footnote{def_2_12.txt - Mathematica code, implementation of definition (3.28). [25].}.

Hereby, let be theorem

**Theorem 3.30.** For every non-negative integers $n \geq 0$ and $m \geq 0$ holds

$$n^V = \begin{cases} \sum_{1 \leq k \leq n} D_m(n, k) = \sum_{1 \leq k \leq n} \sum_{0 \leq j \leq m} A_{m,j}k^j(n - k)^j, & \text{for } V = 2m + 1 \\ \sum_{1 \leq k \leq n} \frac{1}{m} D_m(n, k) = \sum_{1 \leq k \leq n} \frac{1}{n} \sum_{0 \leq j \leq m} A_{m,j}k^j(n - k)^j, & \text{for } V = 2m, \end{cases}$$

where $D_m(n, k)$ is defined by (3.17).

One can verify results concerning above theorem (3.30) via Mathematica code\footnote{expression_2_1.txt - Mathematica code, implementation of theorem (3.30). [26].}. Therefore, theorem (3.30) answers to the question (2.23) positively, since for every $m \geq 0$ exists a triangle, generated by $D_m(n, k)$, $n \geq 0$, $0 \leq k \leq n$, such that odd power $n^{2m+1}$ can be reached as sum of $n$-th row of corresponding triangle over $1 \leq k \leq n$ or $0 \leq k \leq n - 1$. Sequences $A287326$ $A300656$, $A300785$ are partial cases of theorem (3.30) for $m = 1, 2, 3$, respectively.

3.1. **Properties of $D_m(n, k)$ and $A_{m,j}$**. Here we show a few properties of definition $D_m(n, k)$, some of them correlates with properties of partial case $D_1(n, k)$ in 2.15.

1. Sum of $A_{m,j}$ over $j$ in range $0 \leq j \leq m$ gives

$$\sum_{0 \leq j \leq m} A_{m,j} = 2^{2m+1} - 1,$$

where $A_{m,j}$ is defined by (3.28).

2. Similarly to property (2.21) of particular case $D_1(n, k)$, items of $\{D_m(n, k)\}_{k=0}^n$, $m \geq 0$, $n \geq 0$ is symmetric, i.e.

$$D_m(n, k) = D_m(n, n - k),$$

for all $k : 0 \leq k \leq n$.

3. By property (2) for every integer $n \geq 0$, $m \geq 0$ immediately follows

$$n^{2m+1} = \sum_{1 \leq k \leq n} D_m(n, k) = \sum_{0 \leq k \leq n - 1} D_m(n, k)$$

4. For every $m \geq 0$ the $A_{m,m}$ are terms of the sequence $A002457$, [19].

5. For each $m \geq 0$

$$A_{m,0} = 1$$

6. Assume that $n < 0$, then theorem (3.30) can be applied as

$$n^V = \begin{cases} \sum_{1 \leq k \leq |n|} D_m(n, k), & \text{for } V = 2m + 1 \\ \sum_{1 \leq k \leq |n|} \frac{1}{|n|} D_m(|n|, k), & \text{for } V = 2m \end{cases}$$
**Property 3.31. (Linear Recurrence of $D_m(n,k).$)** For every integer $n \geq 0$ in $D_1(n,k), \ D_2(n,k), \ D_3(n,k)$ hold the recurrent relations

\[
\begin{align*}
D_1(n + 1, k) &= 2D_1(n, k) - D_1(n - 1, k) \\
D_2(n + 2, k) &= 3D_2(n + 1, k) - 3D_2(n, k) + D_2(n - 1, k) \\
D_3(n + 3, k) &= 4D_3(n + 2, k) - 6D_3(n + 1, k) + 4D_3(n, k) - D_3(n - 1, k)
\end{align*}
\]

Review the coefficient $D_m(n,k)$, which defined by $m$-order polynomial. It’s well known fact that high order finite difference $\Delta^{m+k}P_m(x) = 0$ for every $x$, where $P_m(x)$ is $m$ order polynomial and $k > 0$. Recall Binomial Transform of sequence $a_n$. D. E. Knuth \[5\] has introduced the binomial transform by

\[
\hat{a}_n = \sum_{k=0}^{n} \binom{n}{k} (-1)^k a_k,
\]

In particular, $\hat{a}_n = \Delta^n a_n$, therefore, for $D_m(n,k)$ we have

\[
\forall t \geq m : \quad \hat{D}_m(n,k)_t = \sum_{j \geq 0} \left( (-1)^j \binom{t + 1}{j} D_m(n + t - j, k) \right) \equiv 0,
\]

hereby, it gives us right to represent recursively every value of $D_m(n + r,k)$, $0 \leq r \leq t + 1$ as

\[
(-1)^{r + 1} \binom{t + 1}{r} D_m(n + t - r, k) = \sum_{j \in \mathbb{Z}_{\geq 0}/\{r\}} (-1)^{j + 1} \binom{t + 1}{j} D_m(n + t - j, k)
\]

In particular,

\[
D_m(n + t, k) = \sum_{j \geq 1} (-1)^{j + 1} \binom{t + 1}{j} D_m(n + t - j, k)
\]

\[
\square
\]

Hereby, let be theorem

**Theorem 3.36.** By property (3.31), particularly, from expression (3.33), for every integer $t \geq m$ follows

\[
(n + t)^{2m + 1} = \sum_{k \geq 1} \sum_{j \geq 1} (-1)^{j + 1} \binom{t + 1}{j} D_m(n + t - j, k)
\]

\[
\square
\]

**3.2. Example of use of theorem (3.30).** In this subsection we show a detailed application of theorem (3.30). In this subsection we highlight the corresponding terms of $A_{m,j}$, $0 \leq j \leq m$ and $T(n,k)$, $1 \leq k \leq n$ with different colors to be more easily to see regularity. Recall existing pattern, that is triangle of coefficients $A_{m,j}$ defined by (3.28)

\[
\begin{array}{ccccccc}
m = 0 & 1 \\
m = 1 & 1 & 6 \\
m = 2 & 1 & 0 & 30 \\
m = 3 & 1 & -14 & 0 & 140 \\
m = 4 & 1 & -120 & 0 & 0 & 630 \\
m = 5 & 1 & -1386 & 660 & 0 & 0 & 2772 \\
\end{array}
\]

Figure 9. Triangle generated by $A_{m,j}$, $m \geq 0$, $0 \leq j \leq m$. 
By received formula \( \sum_{1 \leq k \leq n} \sum_{j \geq 0} D_m(n, k) = n^{2m+1} \) each line of above triangle being multiplied by \( T^{j>0}(n, k) := k^j(n-k)^j \) and summed up to \( n \) or \( n-1 \) over \( k \) from 0 or 1, respectively, will result odd power of \( n^{2m+1} \), depending on the row \( A_{m,j} \), \( 0 \leq j \leq m \) is applied. Consider the case \( n = 3, m = 2 \), we introduce triangle built using \( T(n, k) := k(n-k) \), \( n \geq 1, 1 \leq k \leq n \) as upper triangular array, let be \( 1 \leq n \leq 5, 1 \leq k \leq n \)

\[
\begin{array}{ccccc}
n = 1 & n = 2 & n = 3 & n = 4 & n = 5 \\
0 & 1 & 2 & 3 & 4 \\
0 & 2 & 4 & 6 & \\
0 & 3 & 6 & \\
0 & \\
\end{array}
\]

(3.38)

Figure 10. Upper right triangle generated by \( T(n, k) = k(n-k), n \geq 1, 1 \leq k \leq n \), sequence [A094053, [29] in OEIS.

**Example 3.39.** Consider theorem (3.30) let be \( n = 3 \) and \( m = 2 \), then

\[
3^{2\cdot3+1} = 1 \cdot 2^0 + 0 \cdot 2^1 + 30 \cdot 2^2 + 1 \cdot 2^0 + 0 \cdot 2^1 + 30 \cdot 2^2 + 1 \cdot 0^0 + 0 \cdot 0^1 + 30 \cdot 0^2
\]

= 121 + 121 + 1 = 243

Items in above array are terms of the third row of triangle [A300656]

**Example 3.40.** Consider theorem (3.30) let be \( n = 3 \) and \( m = 3 \), then

\[
3^{2\cdot3+1} = 1 \cdot 2^0 - 14 \cdot 2^1 + 0 \cdot 2^2 + 140 \cdot 2^3 + 1 \cdot 2^0 - 14 \cdot 2^1 + 0 \cdot 2^2 + 140 \cdot 2^3 + 1 \cdot 0^0 - 14 \cdot 0^1 + 0 \cdot 0^2 + 140 \cdot 0^3
\]

= 1093 + 1093 + 1 = 2187

Items in above array are terms of the third row of triangle [A300785]

**Example 3.41.** Consider theorem (3.30) let be \( n = 4 \) and \( m = 3 \), then

\[
4^{2\cdot3+1} = 1 \cdot 3^0 - 14 \cdot 3^1 + 0 \cdot 3^2 + 140 \cdot 3^3 + 1 \cdot 3^0 - 14 \cdot 3^1 + 0 \cdot 3^2 + 140 \cdot 3^3 + 1 \cdot 0^0 - 14 \cdot 0^1 + 0 \cdot 0^2 + 140 \cdot 0^3
\]

= 3739 + 8905 + 3739 + 1 = 16384

Items in above array are terms of the forth row of triangle [A300785]. We can perform same result for \( 4^{2\cdot3+1} \) in terms of multiplication of certain matrices,

\[
4^{2\cdot3+1} = [1, 1, 1] \cdot \begin{bmatrix} 3^0 & 3^1 & 3^2 & 3^3 \\ 4^0 & 4^1 & 4^2 & 4^3 \\ 3^0 & 3^1 & 3^2 & 3^3 \\ 0^0 & 0^1 & 0^2 & 0^3 \end{bmatrix} \begin{bmatrix} 1 \\ -14 \\ 0 \\ 140 \end{bmatrix}
\]
Example 3.42. Consider theorem (3.30) let be $n = 5$ and $m = 3$, then
\[
5^{2\cdot 3+1} = 1 \cdot 4^0 - 14 \cdot 4^1 + 0 \cdot 4^2 + 140 \cdot 4^3 \\
+ 1 \cdot 6^0 - 14 \cdot 6^1 + 0 \cdot 6^2 + 140 \cdot 6^3 \\
+ 1 \cdot 6^0 - 14 \cdot 6^1 + 0 \cdot 6^2 + 140 \cdot 6^3 \\
+ 1 \cdot 4^0 - 14 \cdot 4^1 + 0 \cdot 4^2 + 140 \cdot 4^3 \\
+ 1 \cdot 0^0 - 14 \cdot 0^1 + 0 \cdot 0^2 + 140 \cdot 0^3 \\
= 8905 + 30157 + 30157 + 8905 + 1 = 78125
\]

Items in above array are terms of the fifth row of triangle [A300785].

Example 3.43. Consider theorem (3.30) let be $n = 5$ and $m = 4$, then
\[
5^{2\cdot 4+1} = 1 \cdot 4^0 - 120 \cdot 4^1 + 0 \cdot 4^2 + 0 \cdot 4^3 + 630 \cdot 4^4 \\
+ 1 \cdot 6^0 - 120 \cdot 6^1 + 0 \cdot 6^2 + 0 \cdot 6^3 + 630 \cdot 6^4 \\
+ 1 \cdot 6^0 - 120 \cdot 6^1 + 0 \cdot 6^2 + 0 \cdot 6^3 + 630 \cdot 6^4 \\
+ 1 \cdot 4^0 - 120 \cdot 4^1 + 0 \cdot 4^2 + 0 \cdot 4^3 + 630 \cdot 4^4 \\
+ 1 \cdot 0^0 - 120 \cdot 0^1 + 0 \cdot 0^2 + 0 \cdot 0^3 + 630 \cdot 0^4 \\
= 160801 + 815761 + 815761 + 160801 + 1 = 1953125
\]

4. Another power identity

Review the Corollary (2.2) it says that partial case of theorem (3.30) returns the binomial of the form
\[
\sum_{M \leq k \leq N} D_1(n, k) = \begin{cases} 
U_1(T, 0)n^0 + U_1(T, 1)n^1, & \text{if } M = 1, N = T \\
U_1(T - 1, 0)n^0 + U_1(T - 1, 1)n^1, & \text{if } M = 0, N = T - 1 
\end{cases}
\]
\[
= n^2, \text{ as } T \to n.
\]

Let extend this idea, as we have complete theorem (3.30). We rewrite theorem (3.30) for odd powers as
\[
\sum_{M \leq k \leq N} D_m(n, k) = \begin{cases} 
U_m(T, 0)n^0 + \cdots + U_m(T, m)n^m, & \text{if } M = 1, N = T \\
U_m(T - 1, 0)n^0 + \cdots + U_m(T - 1, m)n^m, & \text{if } M = 0, N = T - 1 
\end{cases}
\]
\[
= n^{2m+1}, \text{ as } T = n.
\]

Above expression is so-called 'closed form' of the theorem (3.30) for every particular $n$. Below we place a few examples of polynomials $\sum_{0 \leq k \leq m} (-1)^{m-k}U_m(T, k) \cdot n^k$, where $m = 2$,

\[
\begin{array}{c|c|c|c}
T & U_2(T, 0)n^0 + U_2(T, 1)n^1 + U_2(T, 2)n^2 \\
\hline
1 & 31 - 60n + 30n^2 \\
2 & 512 - 540n + 150n^2 \\
3 & 2943 - 2160n + 420n^2 \\
4 & 10624 - 6000n + 900n^2 \\
5 & 29375 - 13500n + 1650n^2 \\
6 & 68256 - 26460n + 2730n^2 \\
7 & 140287 - 47040n + 4200n^2 \\
8 & 263168 - 77760n + 6120n^2 \\
9 & 459999 - 121500n + 8550n^2 \\
10 & 760000 - 181500n + 11550n^2 \\
\end{array}
\]

(4.1)
Figure 11. Table of polynomials generated by $\sum_{1 \leq k \leq T} D_2(n, k) = n^5$ as $T \to n$, see definition (3.17) for $D_2(n, k)$.

Below we show a plots of few first polynomials $\sum_{1 \leq k \leq T} D_2(n, k)$ for $T = 1, 2, 3$ and compare it with corresponding monomial $n^5$ by the theorem (3.30).

Figure 12. Local approximations of monomial $n^5$ by corresponding polynomials $\sum_{1 \leq k \leq T} D_2(n, k)$ for $T = 1, 2, 3$, by theorem (3.30).

We can see that monomial $n^5$ can be easily approximated in neighborhood of every particular natural $n$. The polynomials from figure (11) can be generated using Mathematica code.

To understand the nature of coefficients $U_m(T, k)$, let derive them directly by means of theorem (3.30).

(4.2)
\[
\sum_{k=1}^{n} \sum_{j=0}^{m} A_{m,j} k^j (n-k)^j = \sum_{k=1}^{n} A_{m,0} k^0 (n-k)^0 + \cdots + A_{m,m} k^m (n-k)^m
\]
\[
= \sum_{k=1}^{n} A_{m,0} k^0 (n-k)^0 + \sum_{k=1}^{n} A_{m,1} k^1 (n-k)^1 + \cdots + \sum_{k=1}^{n} A_{m,m} k^m (n-k)^m
\]
\[
= A_{m,0} \sum_{k=1}^{n} k^0 (n-k)^0 + A_{m,1} \sum_{k=1}^{n} k^1 (n-k)^1 + \cdots + A_{m,m} \sum_{k=1}^{n} k^m (n-k)^m
\]
\[
= n^{2m+1}.
\]

By the binomial theorem,
\[
\sum_{k=0}^{n-1} (n-k)^j = \sum_{k=0}^{n-1} i \binom{j}{i} n^i (-1)^i k^{j-i}
\]

Mathematica code, generates the polynomials from figure (11). If necessary, one could re-define $m \geq 0$ within the code.
We rewrite the main result of (4.2) as

\[ \begin{align*}
A_{m,0} \sum_{k=1}^{n} k^0(n-k)^0 + A_{m,1} \sum_{k=1}^{n} k^1(n-k)^1 + \cdots + A_{m,m} \sum_{k=1}^{n} k^m(n-k)^m \\
= A_{m,0} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{0}{i} n^0(-1)^i k^0 + \binom{1}{i} n^1(-1)^i k^1 + \binom{2}{i} n^2(-1)^i k^2 + \cdots + \binom{m}{i} n^m(-1)^i k^m \right) \\
+ A_{m,2} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{2}{i} n^2(-1)^i k^2 + \binom{3}{i} n^3(-1)^i k^3 + \cdots + \binom{m}{i} n^m(-1)^i k^m \right) \\
+ A_{m,3} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{3}{i} n^3(-1)^i k^3 + \binom{4}{i} n^4(-1)^i k^4 + \cdots + \binom{m}{i} n^m(-1)^i k^m \right) \\
\vdots \\
+ A_{m,m} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{m}{i} n^m(-1)^i k^m \right) \\
= n^{2m+1}.
\end{align*} \]

Rewrite expression (4.3) in extended view

\[ \begin{align*}
A_{m,0} \sum_{k=1}^{n} k^0(n-k)^0 + A_{m,1} \sum_{k=1}^{n} k^1(n-k)^1 + \cdots + A_{m,m} \sum_{k=1}^{n} k^m(n-k)^m \\
= A_{m,0} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{0}{i} n^0(-1)^i k^0 + \binom{1}{i} n^1(-1)^i k^1 \right) \\
+ A_{m,2} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{2}{i} n^2(-1)^i k^2 + \binom{3}{i} n^3(-1)^i k^3 \right) \\
+ A_{m,3} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{3}{i} n^3(-1)^i k^3 + \binom{4}{i} n^4(-1)^i k^4 \right) \\
\vdots \\
+ A_{m,m} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{m}{i} n^m(-1)^i k^m \right) \\
= n^{2m+1}.
\end{align*} \]

Let rewrite expression (4.4) again and move sigma notation under the brackets,

\[ \begin{align*}
n^{2m+1} = A_{m,0} \sum_{k=1}^{n} k^0(n-k)^0 + \cdots + A_{m,m} \sum_{k=1}^{n} k^m(n-k)^m \\
= A_{m,0} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{0}{i} n^0(-1)^i k^0 \right) + A_{m,1} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{1}{i} n^1(-1)^i k^1 \right) \\
+ A_{m,2} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{2}{i} n^2(-1)^i k^2 \right) \\
+ A_{m,3} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{3}{i} n^3(-1)^i k^3 \right) \\
\vdots \\
+ A_{m,m} \sum_{k=1}^{n} \sum_{i=0}^{n} \left( \binom{m}{i} n^m(-1)^i k^m \right) \\
= n^{2m+1}.
\end{align*} \]
For example, consider the polynomial \( \sum_{k=0}^{m} (-1)^{m-k} U_m(n,k)n^k \), where \( m = 3 \). We derive below a set of coefficients \( U_3(n,0), U_3(n,1), U_3(n,2), U_3(n,3) \)

\[
\begin{align*}
(4.6) \quad \sum_{k=0}^{3} (-1)^{3-k} U_3(n,k)n^k & \equiv A_{3,0} \left[ \sum_{k=1}^{n} \binom{0}{0} n^0 (-1)^0 k^0 \right] + A_{3,1} \left[ \sum_{k=1}^{n} \binom{1}{1} n^1 (-1)^0 k^1 \right] + A_{3,2} \left[ \sum_{k=1}^{n} \binom{2}{0} n^2 (-1)^0 k^2 \right] + A_{3,3} \left[ \sum_{k=1}^{n} \binom{3}{0} n^3 (-1)^0 k^3 \right] \\
& \equiv n^7.
\end{align*}
\]

The coefficients \( U_3(n,0), U_3(n,1), U_3(n,2), U_3(n,3) \) in expression \( [4.6] \) are following

\[
(4.7) \quad U_3(n,0) = A_{3,0} \sum_{k=1}^{n} \binom{0}{0} (-1)^0 k^0 + A_{3,1} \sum_{k=1}^{n} \binom{1}{1} (-1)^1 k^2
\]

\[
+ \quad A_{3,2} \sum_{k=1}^{n} \binom{2}{0} (-1)^2 k^4 + A_{3,3} \sum_{k=1}^{n} \binom{3}{0} (-1)^3 k^6,
\]

\[
(4.8) \quad U_3(n,1) = A_{3,1} \sum_{k=1}^{n} \binom{1}{0} (-1)^0 k^1 + A_{3,2} \sum_{k=1}^{n} \binom{2}{1} (-1)^1 k^3
\]

\[
+ \quad A_{3,3} \sum_{k=1}^{n} \binom{3}{2} (-1)^2 k^5,
\]

\[
(4.9) \quad U_3(n,2) = A_{3,2} \sum_{k=1}^{n} \binom{2}{0} (-1)^0 k^2 + A_{3,3} \sum_{k=1}^{n} \binom{3}{1} (-1)^1 k^4
\]

\[
(4.10) \quad U_3(n,3) = A_{3,3} \sum_{k=1}^{n} \binom{3}{0} (-1)^0 k^3.
\]

Let rewrite above identities in compact form as,

\[
(4.11) \quad U_3(n, r = 0) = \sum_{t \geq 0}^{3} A_{m,t} \sum_{t \in (t-1)}^{n} \binom{t}{t} (-1)^t t^{2t}
\]

\[
= \sum_{t \geq 0}^{3} \sum_{t \in (t-1)}^{n} A_{m,t} \binom{t}{t} (-1)^t t^{2t}
\]

\[
(4.12) \quad U_3(n, r = 1) = \sum_{t \geq 1}^{3} A_{m,t} \sum_{t \in (t-1)}^{n} \binom{t}{t-1} (-1)^{t-1} t^{2t-1}
\]
Similarly, the coefficients $U_{m}(n, r)$ derived just by changing the iteration limits within the sum

$$
U_{m}(n - 1, r) \overset{\text{def}}{=} \sum_{t \geq r}^{n-1} A_{m,t} \left( \begin{array}{c} t \\ t-r \end{array} \right) (-1)^{t-r} \ell^{2t-r}
$$

Similarly, the coefficients $U_{m}(n, r)$ derived just by changing the iteration limits within the sum

$$
U_{m}(n, r) \overset{\text{def}}{=} \sum_{t \geq r}^{n} A_{m,t} \left( \begin{array}{c} t \\ t-r \end{array} \right) (-1)^{t-r} \ell^{2t-r}
$$

In above equation (4.16) it must be defined $\ell^{0} = 1$ for all $\ell$, see [31]. Mathematica implementations of expressions (4.15) and (4.16) are available in [41], [42]. Therefore, for every $n \geq 1$, and $m \geq 0$, we have identity

$$
n^{2m+1} = \sum_{0 \leq r \leq m} (-1)^{m-r} U_{m}(n, r) \cdot n^{r}
$$

Expressions (4.17), (4.18) are analogs to Faulhaber’s odd power identity, see property (2.3) and [21], p. 9. Expressions (4.17), (4.18) could be verified via Mathematica codes [40]. Here we’d like
to show a few examples of polynomials generated by $\sum_{0 \leq k \leq T-1} D_2(n, k)$, see definition (3.17) for $D_2(n, k)$

\[
\begin{array}{c|c}
T & U_2(T - 1, 0)n^0 + U_2(T - 1, 1)n^1 + U_2(T - 1, 2)n^2 \\
\hline
1 & 1 \\
2 & 32 - 60n + 30n^2 \\
3 & 513 - 540n + 150n^2 \\
4 & 2944 - 2160n + 420n^2 \\
5 & 10625 - 6000n + 900n^2 \\
6 & 29376 - 13500n + 6120n^2 \\
7 & 68257 - 26460n + 2730n^2 \\
8 & 140288 - 47040n + 4200n^2 \\
9 & 263169 - 77760n + 6120n^2 \\
10 & 460000 - 121500n + 8550n^2 \\
\end{array}
\]

(4.19)

Figure 13. Table of polynomials generated by $\sum_{0 \leq k \leq T-1} D_2(n, k)$.

Below we show a plots of few first polynomials $\sum_{1 \leq k \leq T-1} D_2(n, k)$ for $T = 1, 2, 3, 4$ and compare it with corresponding monomial $n^5$ by theorem (3.30).

![Figure 14. Local approximations of monomial $n^5$ by corresponding polynomials $\sum_{1 \leq k \leq T-1} D_2(n, k)$ for $T = 1, 2, 3, 4$, by theorem (3.30).](image)

The polynomials from figure (13) can be generated using Mathematica code. Additionally, the generalized binomial series could be reached by means of identity

\[
\sum_{M \leq k \leq N} D_1(n, k) = \begin{cases} 
U_1(T, 0)n^0 + U_1(T, 1)n^1, & \text{if } M = 1, \ N = T \\
U_1(T - 1, 0)n^0 + U_1(T - 1, 1)n^1, & \text{if } M = 0, \ N = T - 1 
\end{cases}
= n^3, \text{ as } T \to n.
\]

For instance, for every natural $n$

\[
n^3 = U_1(T, 0) \cdot n^0 + U_1(T, 1) \cdot n^1
\]

To reach higher power $m$, let just multiply this identity by $n^{m-3}$,

\[
n^m = U_1(T, 0) \cdot n^{m-2} + U_1(T, 1) \cdot n^{m-3}
\]

[Um(n,k)coefficients.txt] - Mathematica code, generates the polynomials from figure (12). If necessary, one could re-define $m \geq 0$ within the code.
Let rewrite this expression regarding to itself as recursion,

\[ n^m = U_1(T, 0) \cdot [U_1(T, 0)n^{m-4} + U_1(T, 1)n^{m-5}] + U_1(T, 1) \cdot [U_1(T, 0)n^{m-5} + U_1(T, 1)n^{m-6}] \]
\[ = U_1(T, 0)^2 \cdot n^{m-4} - 2 \cdot U_1(T, 0) \cdot U_1(T, 1)n^{m-5} + U_1(T, 1)^2 \cdot n^{m-6} \]

Repeating above process similarly \( j \geq 1 \) times, we have

\[
(4.20) \quad n^m = \sum_{k \geq 0} (-1)^k \left( \frac{j}{k} \right) U_1(T, 0)^{j-k} \cdot U_1(T, 1)^k \cdot n^{m-2j-k}
\]
\[
= \sum_{k \geq 0} (-1)^k \left( \frac{j}{k} \right) U_1(T - 1, 0)^{j-k} \cdot U_1(T - 1, 1)^k \cdot n^{m-2j-k}
\]

We believe we can perform similarly in terms of multinomial coefficients,

\[
(4.21) \quad n^m = \sum_{k_1+k_2+\ldots+k_t=j} \left( \binom{j}{k_1, k_2, \ldots, k_t} \right) \prod_{\ell=1}^{t} (-1)^{\ell} U_1(T, \ell)^{k_\ell} \cdot n^{m-(t+1)j-k}
\]
\[
= \sum_{k_1+k_2+\ldots+k_t=j} \left( \binom{j}{k_1, k_2, \ldots, k_t} \right) \prod_{\ell=1}^{t} (-1)^{\ell} U_1(T - 1, \ell)^{k_\ell} \cdot n^{m-(t+1)j-k}.
\]

Note that we must set \( T = n \) in above identities. Another way to represent odd-powered monomial \( n^{2m+1}, \ m = 0, 1, 2, \ldots \) is to define a polynomial \( U_m(n, k) \). As \( \sum_{0 \leq k \leq m} (-1)^{m-k} U_m(n, k) \cdot n^k = \sum_{0 \leq k \leq m} (-1)^{m-k} U_m(n - 1, k) \cdot n^k \), it follows that

\[
2n^{2m+1} = \sum_{0 \leq k \leq m} (-1)^{m-k} U_m(n, k) \cdot n^k + \sum_{0 \leq k \leq m} (-1)^{m-k} U_m(n - 1, k) \cdot n^k
\]
\[
= \sum_{0 \leq k \leq m} (-1)^{m-k} (U_m(n, k) + U_m(n - 1, k)) \cdot n^k,
\]

Let be definition

\[
(4.22) \quad U_m(n, k) \overset{\text{def}}{=} \frac{1}{2} \left[ U_m(n, k) + U_m(n - 1, k) \right],
\]

Therefore,

\[
(4.23) \quad n^{2m+1} = \sum_{0 \leq k \leq m} U_m(n, k) \cdot n^k.
\]

Expression \( 4.23 \) generates the following polynomials given \( m = 2 \),

\[
\begin{array}{|c|c|c|}
\hline
T & \mathcal{U}_2(T, 0)n^0 + \mathcal{U}_2(T, 1)n^1 + \mathcal{U}_2(T, 2)n^2 \\
\hline
1 & 16 - 30n + 15n^2 \\
2 & 272 - 300n + 90n^2 \\
3 & 1728 - 1350n + 285n^2 \\
4 & 6784 - 4080n + 660n^2 \\
5 & 20000 - 9750n + 1275n^2 \\
6 & 48816 - 19980n + 2190n^2 \\
7 & 104272 - 36750n + 3465n^2 \\
8 & 201728 - 62400n + 5160n^2 \\
9 & 361584 - 99630n + 7335n^2 \\
10 & 610000 - 151500n + 10050n^2 \\
\hline
\end{array}
\]

Figure 15. Table of polynomials generated by \( \sum_{0 \leq k \leq m} U_m(T, k) \cdot n^k \), where \( T = 1, 2, 3, .., 10 \).
Polynomials from Figure (15) could be generated using Mathematica code\textsuperscript{10}. Let graphically show an approximation of monomial $n^5$ by polynomials $\sum_{0 \leq k \leq m} U_2(T, k) \cdot n^k$ for $T = 1, 2, 3, 4$.

![Figure 16. Local approximations of monomial $n^5$ by corresponding polynomials $\sum_{0 \leq k \leq m} U_2(T, k) \cdot n^k$ for $T = 1, 2, 3, 4$.](image)

Definition (4.22) of coefficients $U_m(n, k)$ and identity (4.23) could be verified via Mathematica codes\textsuperscript{11, 12} respectively. Similarly to (4.20), (4.21) we can perform a binomial and multinomial representation of monomial $n^m$, where $n, m$ are non-negative integers and $T = n$,

$$n^m = \sum_{k \geq 0} (-1)^k \binom{j}{k} U_1(T, 0)^{j-k} \cdot U_1(T, 1)^k \cdot n^{m-2j-k}$$

(4.25)

And

$$n^m = \sum_{k_1+k_2+\ldots+k_t=j} \binom{j}{k_1, k_2, \ldots, k_t} \prod_{\ell=1}^{t} (-1)^\ell U_1(T-1, \ell)^{k_\ell} \cdot n^{m-(t+1)j-k}$$

(4.26)

5. ACKNOWLEDGEMENTS

We would like to thank to Dr. Max Alekseyev (Department of Mathematics and Computational Biology, George Washington University) for sufficient help in deriving of $A_{m,j}$ coefficients, Dr. Hansruedi Widmer for useful comments concerning system of equations (3.19), Dr. Ron Knott (Visiting Fellow, Dept. of Mathematics at University of Surrey) for useful suggestions on writing of this article, and to Mr. Albert Tkaczyk for providing an analogs of triangle (2.14) for powers $m = 5, 7$, that are sequences A300656, A300785 respectively. Also, we’d like to thank to OEIS editors Michel Marcus, Peter Luschny, Jon E. Schoenfield and others for their patient and faithful volunteer work and for useful comments and suggestions during edition of sequences, concerned with this manuscript. We, also, thank to Tatyana Dryahlova for her help in translating of this manuscript in Russian.

\textsuperscript{10} Combined\_U\_m(n,k)\_coefficients\_polynomials\_gf.txt - Mathematica code, generates the polynomials from Figure 15.

\textsuperscript{11} Combined\_U\_m(n,k)\_coefficients\_gf.txt - Mathematica code, verifies the values definition (4.22) produces.

\textsuperscript{12} Combined\_U\_m(n,k)\_coefficients\_odd\_power\_identity.txt - Mathematica code, verifies identity (4.23).
6. Conclusion

In this paper particular pattern, that is binomial distributed triangle \[ \text{A287326} \] in OEIS, which shows perfect cube \( n \) as sum of row terms over \( 0 \leq k \leq n - 1 \) or \( 1 \leq k \leq n \) is generalized, in this manuscript are found and discussed the polynomials \( D_m(n,k) \) and \( U_m(n,k) \), such that, when being summed up over \( k \) in some range with respect to \( m \) and \( n \) returns the monomial \( n^{2m+1} \).

As first step, we discussed analogs of \[ \text{A287326} \] for powers \( l = 5, 7 \), sequences \[ \text{A300656}, \text{A300785} \], respectively, then we derived coefficients \( A_{m,j} \), such that for every \( n \geq 0 \) and \( m \geq 0 \) holds

\[
n^{2m+1} = \sum_{1 \leq k \leq n} D_m(n,k),
\]

where

\[
D_m(n,k) := A_{m,m}k^m(n-k)^m + A_{m,m-1}k^{m-1}(n-k)^{m-1} + \cdots + A_{m,0}k^0(n-k)^0,
\]

and \( A_{m,j} \) is defined by (3.28). Therefore, question (2.23) is answered positively. Section 3.1, respectively. Relation between Faulhaber’s sum \( \sum n^m \) and finite differences of power are shown in [2.3].

In section 4 we have generalized the main result of Corollary (2.2) for all odd powers of the form \( 2m + 1 \), \( m = 0, 1, 2, ... \) and proven an identities

\[
n^{2m+1} = \sum_{0 \leq r \leq m} (-1)^{m-r}U_m(n,r) \cdot n^r
\]

\[
= \sum_{0 \leq r \leq m} (-1)^{m-r}U_m(n-1,r) \cdot n^r.
\]

7. Application 1. Extended tables of polynomials, consisting $U_m(n, k)$ coefficients

In this application we attach an extended table, consisting of polynomials, generated by $\sum_{1 \leq k \leq T} D_m(n, k)$ and $\sum_{0 < k < T - 1} D_m(n, k)$ for various $t$ and $m$. We begin from cases $m = 2, 3, 4$ given generating function $\sum_{1 \leq k \leq T} D_m(n, k)$ and continue similarly with examples for $\sum_{0 < k < T - 1} D_m(n, k)$. The following tables could be generated using Mathematica code $\text{Um}(n,k)\_coefficients\_polynomials\_gf.txt$. Here we begin to show our tables for $m = 1, 2, 3, 4$ and $T = 1, 2, ..., 40$
