This article attempts to clarify an issue regarding the proper definition of plastic dislocation density tensor. This study shows that the Ortiz’s and Berdichevsky’s plastic dislocation density tensors are equivalent with each other, but not with Kondo’s one. To fix the problem, we propose a modified version of Kondo’s plastic dislocation density tensor.

Keywords: elasto-plasticity, deformation gradient, plastic dislocation density tensor

Plastic deformation is everywhere, from bending a fork to panel beating a car body. It is easy to be intrigued by a subject that pervades so many aspects of peoples’ daily lives.

G.I. Taylor [1] realized that plastic deformation could be explained in terms of the theory of dislocations, even since this view has become a consensus that mechanism of plastic deformation is the result of dislocation accumulation [1–19, 22–24]. Accordingly, some plastic dislocation density tensors have been proposed [2–8]. However, they are totally different from each other and no any consensus in terms of definition of the plastic dislocation density tensor. The majority of past and contemporary authors following the original idea of Kondo [2, 5, 6] and Bilby et al. [4], adopted the following definition of the resultant Burgers vector.

\[
b_{\text{Kondo}} = F^e \oint c F^{e-1} \cdot dx = -F^e \oint (F^{e-1} \times \nabla) \cdot dA,
\]

where \( c \) is any close contour in the current configuration. Ortiz and Repetto [7] defined the resultant Burgers vector in a completely different way.

\[
b_{\text{Ortiz}} = \oint F^p \cdot dx = -\oint F^p \times \nabla \cdot dA = \oint T_{\text{Ortiz}} \cdot dA.
\]

Reina et al. [11–14] did a comprehensive and in depth studies on the Ortiz’s definition. Berdichevsky [8] introduced a measure of the resultant closure failure leading to the dislocation density tensor.

\[
T_{\text{Berdichevsky}} = -F^p \cdot (F^p \times \nabla).
\]

Le et al. [15–19] recommended to use Berdichevsky’s definition.

It is clear that a unification of the definition for plastic dislocation density tensor is still an issue. which the above-mentioned definition is the proper one? What is the relationship between those definitions? If the definition is not well defined, how to fix it?

Phenomenologically the total elasto-plastic deformation gradient \( F = g_i \otimes G^i = F_{ij}^i g^j \otimes G^j = F_{ij}^i g^j G^j \) can be decomposed into the multiplication of elastic gradient namely \( F = F^e F^p \), is due to Bilby et al. [3], Körner [6], Lee and Liu [20], and Lee [21]. The elastic deformation gradient \( F^e = g_i \otimes e^i = F_{ij}^i g^j \otimes e^j = F_{ij}^i g^j e^j \) and plastic gradient \( F^p = e_i \otimes G^i = F_{ij}^p e^i \otimes G^j = F_{ij}^p e^i G^j \), \( G_i \), \( e_i \), \( g_i \) are the base vectors corresponding to the reference, intermediate and current configuration, respectively. The deformation decomposition is shown in Figure 1.

It should be noted that the elastic deformation \( F^e \) and plastic deformation \( F^p \) cannot be gradients of global maps, they are therefore called incompatible, namely \( F^e \times \nabla \neq 0 \) and \( F^p \times \nabla \neq 0 \) as well, where the operator \( \nabla = G^k \nabla_k \) is gradient operator, and \( \nabla_k \) is covariant derivative in reference configuration. Nevertheless, both \( F^e \) and \( F^p \) are orientation preserving so that \( J_p = \det(F^p) > 0 \) and \( J_e = \det(F^e) > 0 \). This means, \( F^p \) and \( F^e \) have inverse deformations, denoted correspondingly by \( (F^p)^{-1} \) and \( (F^e)^{-1} \).

In this short article, we will show that the Ortiz’s and Berdichevsky’s

\*Bohua Sun, On plastic dislocation density tensor, Results in Physics, Volume 12, March 2019, Pages 886-887.
plastic dislocation density tensor are equivalent, while not equivalent with Kondo’s one. To fix Kondo’s problem, we can change Kondo’s definition to following form

\[ b_{\text{Modified-Kondo}} = \int c \cdot F^{-1} \cdot dA \]

\[ = - \int \int (F^{-1} \times \nabla) \cdot dA \]

\[ = \int \int T_{\text{Modified-Kondo}} \cdot dA, \quad (1) \]

Thus, we have modified Kondo’s plastic dislocation density tensor as follows

\[ T_{\text{Modified-Kondo}} = - F^{-1} \times \nabla. \quad (2) \]

With this modified definition, later we will show that the modified Kondo’s definition can be equivalent with both Ortiz’s and Berdichevsky’s plastic dislocation density tensor. To verify these, we need to prove a tensor identity at first.

**Lemma 1** Giving two 2nd order tensors \( A = g_i \otimes e^i = A_{ij} g^i \otimes e^j \) and \( B = e_i \otimes G^i = B_{ij} e^i \otimes G^j = B_{ij} e^i G^j \), then we have tensor identity: \( (A \otimes B) \times \nabla = A \cdot (B \times \nabla) + (A \times \nabla) \cdot B \).

**Proof 2**

\[ (A \otimes B) \times \nabla = (A \cdot B) \times G^m \nabla_m \]

\[ = [(A \nabla_m) \cdot B + A \cdot (B \nabla_m)] \times G^m \]

\[ = A \cdot (B \nabla_m) \times G^m + (A \nabla_m) \cdot B \times G^m, \quad (3) \]

where \( A \cdot (B \nabla_m) \times G^m = A \cdot (B \times \nabla) \), and

\[
\begin{align*}
(A \nabla_m) \cdot B \times G^m &= [(A \nabla) \cdot G_m] \cdot [B_{kl} e^k G^l \times G^m] \\
&= A \nabla \cdot B_{kl} (e^k \cdot G_m) (G^l \times G^m) \\
&= A \nabla \cdot B_{kl} (e^k \cdot G_m) (G_m G^m) = A \nabla \cdot B \times I \\
&= -A \nabla \times B = -A \nabla \times (I \cdot B) \\
&= -(A \nabla \times I) \cdot B = (A \times \nabla) \cdot B,
\end{align*}
\]

where the unit tensor \( I = G_m G^m = \delta_{ij} G^i G^j \) in reference configuration. Therefore, we have proven the tensor identity, which has never been seen in literature.

Despite the incompatibility of elastic and plastic deformation, namely, \( F^e \) and \( F^p \), the total deformation \( F \) is compatible, it means that the total deformation must be gradient of global maps, thus it must satisfy compatible condition \([23]\), namely, the incompatible tensor \( Inc(F) = F \times \nabla = 0 \), which leads to \( Inc(F) = (F^e \cdot F^p) \times \nabla = 0 \).

Applying the identity of tensor proved in the Lemma, we have

\[ Inc(F) = F \times \nabla = (F^e \cdot F^p) \times \nabla \]

\[ = F^e \cdot (F^p \times \nabla) + (F^e \times \nabla) \cdot F^p = 0. \quad (5) \]

Notice \( F^e \cdot F^{-1} \times \nabla = I \times \nabla = 0 \), namely, \( F^e \times \nabla = -F^e \cdot (F^{-1} \times \nabla) \cdot F^e \).

Using the previous definitions of plastic dislocation density tensor, the above expression can be rewritten as

\[ Inc(F) = F^e \cdot (-T_{\text{Ortiz}}) + (-F^e \cdot T_{\text{Modified-Kondo}}) \cdot F \]

\[ = F \cdot (-T_{\text{Berdichevsky}}) + (-F^e \cdot T_{\text{Modified-Kondo}}) \cdot F \]

\[ = 0. \quad (6) \]

Therefore, we have their relationships:

\[ T_{\text{Ortiz}} + T_{\text{Modified-Kondo}} \cdot F = 0, \quad (7) \]

\[ F \cdot T_{\text{Berdichevsky}} + F^e \cdot T_{\text{Modified-Kondo}} \cdot F = 0, \quad (8) \]

\[ F \cdot T_{\text{Berdichevsky}} + T_{\text{Ortiz}} \cdot F^e \cdot F^{-1} \cdot F^p = 0. \quad (9) \]

Clearly the relations \( 7,8 \) and \( 9 \) reveal that three definition of the plastic dislocation tensor are equivalent.

In summary, this study shows that both Ortiz’s and Berdichevsky’s plastic dislocation density tensors are equivalent, and are proper definition. Although Kondo’s definition is not proper one, it can be fixed by the modified version in Eq. 2.
