Abstract: In 2016, the global environmental impact of greenhouse gas (GHG) emissions was 49.3 gigatons CO₂ equivalent. Worldwide, the transportation sector is responsible for 14% of GHG. Electric vehicles (EV) powered by less-polluting energy sources are one way to reduce the environmental impact of the transportation sector, but immediate transportation demands cannot be met by existing EV technology. Use of less polluting biofuel in place of petroleum-based gasoline or diesel fuel to power the existing transportation fleet is a widely accepted transitional solution, including in the Republic of Korea. The purpose of this research is to investigate approaches to biofuels in the US and the UK in order to evaluate Korea's current energy policies related to use of biofuels and to make recommendations for strengthening Korea's energy policy. This article addresses only policies for use of biodiesel rather than ethanol (widely used in the US) because ethanol is not used in Korea. This research shows that Korea calculates GHG using the principle that biofuel is carbon neutral, but energy policies in the US and the UK treat biofuel as not entirely carbon neutral. Korea should examine how to calculate GHG from biodiesel according to the standard set by the UK in order to work toward a more environmentally sustainable energy policy.

Keywords: RFS (Renewable Fuel Standards); renewable energy; biodiesel; CO₂; GHG; sustainability; carbon neutral

1. Introduction

1.1. Research Objective

The purpose of this paper is to identify the shortcomings of Korea's biodiesel program, including its Renewable Fuel Standard (RFS), and to propose modifications to the program in order to improve the environmental sustainability of biodiesel in Korea. The seventh largest GHG emitting country, Korea is implementing a biodiesel program to improve the sustainability of its energy supply by increasing biodiesel use in the transportation sector [1]. However, while Korea calculates GHG emissions using the principle that biofuel is carbon neutral, energy policies in the US and the UK treat biofuel as not entirely carbon neutral. These countries include GHG emissions of specific biofuel sources and production processes in calculating total GHG emissions for biofuel from various sources.

Recently, the EU publicly announced that it would ban the import of palm oil, one of the biggest sources of GHG emissions among biofuel feedstocks, for use in biofuel as part of the EU's plan to

increase biofuel use while keeping environmental sustainability in view [2]. This is the hottest issue in the biofuel market because the ban on palm oil is regarded not just as the ban of a feedstock in the EU, but also as a trade war between the EU and Indonesia, the world's largest exporter of palm oil. The EU's ban on palm oil is also part of a larger global trend toward greater environmental sustainability in the world's energy supply, a trend that may have important implications for energy policy in Korea. The question of the carbon neutrality of biofuels was raised at the establishment of Korea's RFS program in 2013 and has been acknowledged by the Korean government and related agencies. However, the RFS program has not been modified to address this issue.

The purpose of this research, therefore, is to investigate approaches to the use of biofuels in the US and the UK, to evaluate Korea's current energy policies related to biofuels in comparison to the policies of the US and UK, and to make recommendations for strengthening Korea's energy policy. This article only addresses policies related to biodiesel rather than ethanol (widely used in the US) because ethanol is not used in Korea. The paper is structured as follows. Section 1 describes policies related to biodiesel in the US, EU, UK, and Korea. Section 2 explains data and methods of analysis used to evaluate the sustainability of biofuel usage. Section 3 shows the result of that analysis, specifically with respect to how GHG emissions in Korea would be affected by following the standard set by the UK. Section 4 discusses the implications for Korea's RFS, and Section 5 summarizes the article's recommendations.

1.2. Biofuel in the World Energy Supply

As of 2018, approximately 3% of world road transport fuel is provided by ethanol, biodiesel, and other biofuels. Figure 1 shows the share of worldwide energy provided by traditional, modern, and non-biomass sources in 2015, when about 2.6% of fuel for the world transportation sector, including aviation, came from biofuel [3]. As shown in Figure 2, an estimated 72% of biofuel production was ethanol, 23% biodiesel, and 4% was hydrotreated vegetable oil (HVO).

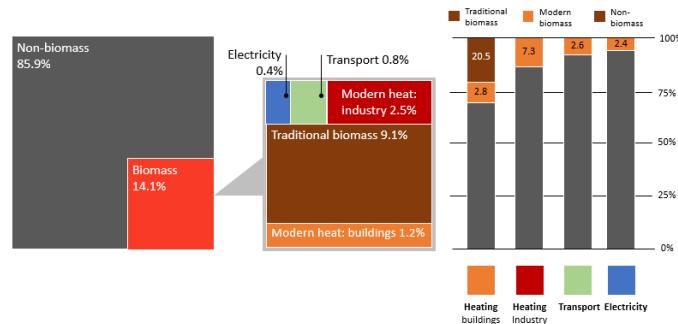

Figure 1. Shares of biomass in total final energy consumption and in final energy consumption by the end-use sector 2015 [3].

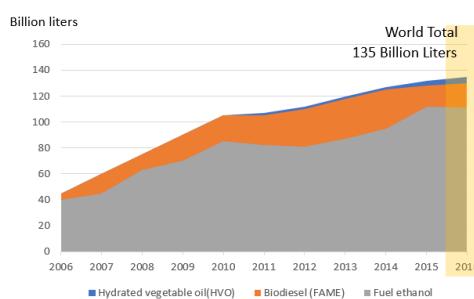

Figure 2. Global trends in ethanol, biodiesel, fatty acid methyl ester (FAME), and HVO production, 2006–2016 [3].

The International Energy Agency's (IEA) 450 Scenario sets out an energy pathway consistent with the goal of limiting the global increase in temperature to 2 °C by limiting concentrations of GHG

in the atmosphere to around 450 parts per million of CO₂eq. According to the 450 Scenario, biofuel is expected to meet about 17% of the world transportation sector demand for fuel, including in the aviation sector, through the development and deployment of advanced biofuels coming from waste, algae, and cellulosic feedstocks. As shown in Figure 3, the 450 Scenario anticipates that electric vehicles (EV) will increasingly replace light duty combustion engine vehicles and that biofuel will replace refined petroleum products, namely gasoline, diesel, and kerosene [4].

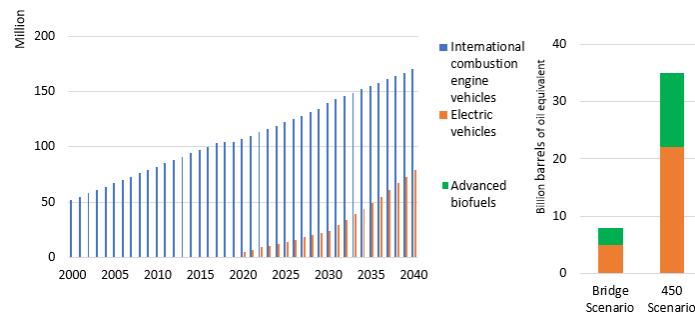

Figure 3. Global sales of light-duty passenger and commercial vehicles by type in the 450 Scenario (left) and global cumulative oil savings resulting from use of EVs and advanced biofuels, 2015–2040.

1.2.1. Biofuel in the US

As shown in Figure 4, use of biofuel in the US has expanded dramatically over the past decade in response to the RFS program, passed by Congress in 2007, which imposed obligations on the part of oil refineries and importers to blend biofuel with conventional fuels [5]. Since 2007, the US has been the largest ethanol-producing country in the world, accounting for 15,800 million gallons in 2017 [6].

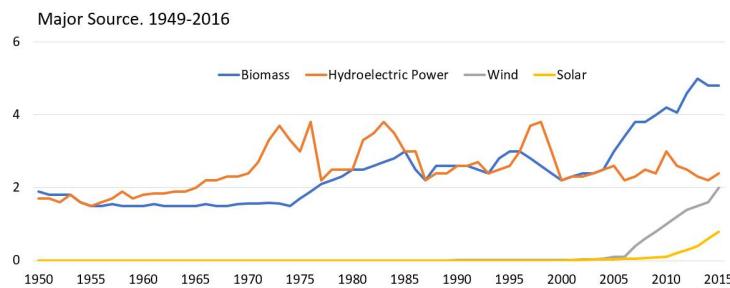

Figure 4. Renewable consumption, quadrillion Btu [7].

Following aggressively expanded production of biofuel in the 2000s, two studies published in 2008 argued that in spite of biofuel's many advantages, use of croplands for biofuels increases GHG when emissions from land use change (LUC) are factored into the equation [8,9]. These studies had a significant impact on the standards for calculating the carbon savings of biofuels over petroleum-based fuels, resulting in the adoption of "lifecycle" based standards that consider the carbon cost of a feedstock throughout its lifecycle, as described below.

An increase in the consumption of biofuel feedstocks leads inevitably to an increase in land used for agriculture in one of two ways: directly, when new cropland is created for the production of biofuel feedstocks, resulting in direct land use change (DLUC), or indirectly, when existing cropland is used for biofuel feedstock production, forcing food, feed, and materials to be produced on new cropland elsewhere, resulting in indirect land use change (ILUC). The two largest biologically active stores of terrestrial carbon are soils and plant biomass, which have 2.7 times more carbon than the atmosphere [8]. Searchinger et al. argued that diverting land from its existing uses led to the sacrifice of carbon sequestration and that GHG calculations had ignored land use change (LUC) emissions [9]. These reports argued that biofuels from waste products, municipal waste, crop-waste, and fall grass

harvests from reserved lands could reduce GHG emissions more than biofuels from specially grown feedstocks [9].

1.2.2. Biofuel in the EU

Before discussing the state of biofuel in the UK, it is necessary to discuss the EU's policies because most of the UK's renewable energy policy is closely related to the EU's Renewable Energy Directive (RED). However, following Brexit, the UK's current stance on the RED is unclear, and the UK has not announced its position with respect to the EU's energy and climate targets [10].

Like the US, the EU is working to increase the proportion of biofuel in the transportation fuel market; however, concerns about ILUC and DLUC in the production of biofuel represent a significant dilemma. In addition to the impact of LUC on GHG emissions, the possibility also exists that diverting agricultural land to the production of feedstocks for biofuel will interfere with the production of food crops for human consumption. To address this concern, the EU's RED (2009/28/EC) specifically ordered the European Commission to develop a methodology for accounting for the effect ILUC. However, ILUC is connected with other factors in agricultural markets at local levels as well as global ones, so its impacts cannot easily be determined [11].

In response to concerns about the environmental impact of biodiesel feedstocks, in January 2018, the European Parliament proposed a ban on the use of vegetable oils like palm oil to produce biodiesel after 2020, which would represent a significant new direction in the EU's use of biofuels [12]. In 2016 and 2017, the EU was one of the largest palm oil importers in the world, importing about seven million tons. Consequently, the EU's ban on biodiesel made from palm oil will also affect the economies of the EU's primary suppliers of palm oil, Indonesia and Malaysia, whose economies depend on palm oil export [13]. The EU accounts for approximately 10% of Indonesia's total palm oil exports [14]. While palm oil may not be an inherently environmentally unsustainable feedstock, use of palm oil as a foundation for carbon mitigation through biodiesel runs the risk of merely transferring the carbon cost from the consuming country to the producing country without fundamentally altering the overall GHG profile [15].

1.2.3. Biofuel in the UK

In 2003, the UK introduced a climate change policy designed to reduce CO₂ emissions 20% by 2010 and 60% by 2050, with increased use of biofuel as one measure to achieve the target. This program came into force in 2008 in the form of the Renewable Transport Fuel Obligation (RTFO) [16]. The RTFO has been one of the UK's main programs to mitigate GHG emissions from the transport sector, and in 2011, it was amended to follow the transport elements of the EU's RED. The RTFO program requires biofuel suppliers to meet its sustainability criteria, including blend ratio, to receive Renewable Transport Fuel Certificates (RTFC). In 2013 the program was expanded to include new renewable fuels [17].

1.2.4. Biofuel in Korea

Korea's RFS, first introduced as a pilot program in 2002, is intended to increase the use of fuel from renewable energy sources in the transportation sector as part of a national effort to reduce GHG emissions. One notable finding of the pilot program was the problem of fuel filters clogging at low temperatures when the biofuel blend ratio was too high. Based on this finding, 0.5% biofuel (B0.5) was established as the minimum blend ratio for biodiesel supplied to the transportation market beginning in 2006, and a tax exemption was enacted to promote use of biodiesel. The RFS program became a regulatory policy in 2012, with a blend ratio of 2% [18]. The current RFS was introduced in 2015 in conjunction with Korea's Intended Nationally Determined Contribution (INDC) plan, which also identified mitigation measures in various sectors [19]. In the transport sector, the INDC continues to increase environment-friendly public transportation and strengthens low-carbon standards. Overall, the most effective way to mitigate GHG directly is to raise the blend ratio of biofuel.

However, at this time, Korea's primary feedstocks for biodiesel are imported palm oil and used cooking oil (UCO). As the blend ratio increases, the share of imported feedstock increases [18].

In January 2018, the Korean government announced an increase in the blend ratio from 2.5% biofuel (B2.5) to 3% biofuel (B3) beginning in 2018 [20]. In response, some of the nation's media argued that this position was in opposition to global trends, especially the EU's decision to ban biodiesel from palm oil, and pointed out a lack of sustainability of biodiesel in Korea [21]. In addition, it was argued that this policy would increase the cost of fuel in the transportation sector [22–24].

Korea was the first nation in Asia to introduce a standard for renewable fuel [18]. However, Korea's RFS does not have a long-term master plan and has a relatively lower blend ratio than other countries' energy policies. For example, the current blend ratio for biodiesel in Korea is B3, while in Thailand, the current mandatory blend ratio is B7. Additionally, unlike the US and the UK, Korea does not have sustainability and carbon-saving criteria for feedstocks [25]. The transportation sector represents about 25% of total energy consumption in Korea, which means that limitations in Korea's approach to sustainability in the transport sector reduce the overall effectiveness of Korea's GHG mitigation plan.

1.3. Comparison of RFS Program by Country

Although Korea's RFS program has superficial similarities to the US's RFS program and the UK's RTFO, the differences are significant. As Table 1 shows, the UK and US programs include sustainability criteria, cover multiple renewable fuels, set long term targets, and include mechanisms by which obligated parties can buy and trade compliance credits. Korea's RFS program includes none of these elements. This analysis focuses specifically on sustainability criteria.

Table 1. Comparison of renewable fuel programs in Korea, the US, and the UK [26–28].

	Korea	US	UK
Program	RFS	RFS	RTFO
Implement agency	KEA, K-Petro	EPA	DfT
Start year	2015	RFS 1: 2007.9~2010.11 RFS 2: 2010.12~2022	2008
Volume target	Blending 3% biodiesel with conventional diesel (2018~2020)	36 billion gallons of renewable fuel by 2022	Biofuel volume - 2018: 7.3%, 2020: 9.8%, 2032: 12.4%
Renewable fuel under the RFS	Biodiesel	Biomass-based diesel Cellulosic and Advanced biofuel Total renewable fuel	Biofuel, partial biofuels, renewable fuels of non-biological origin (RFNBOs) and fuels that are part RFNBO, part non-RFNBO
Obligated parties	Refineries or imports of diesel fuel	Refineries or imports of gasoline or diesel fuel	Suppliers of transport and nonroad mobile machinery fuel
Compliance	Blending biodiesel into transportation fuel	Blending renewable fuels into transportation fuel obtaining credits, Renewable Identification Numbers (RINs) to meet an EPA-specific renewable volume obligation	Mandatory sustainability criteria have to be met for biofuels to be issued with Renewable Transport Fuel Certificates (RTFCs) and count towards suppliers' obligations
Fuel pathway (Sustainability)	All of the biodiesels blended are granted to be 100% GHG reduction, carbon neutral	Lifecycle GHG reduction (as compared to a 2005 petroleum baseline) - Biomass based diesel: 50% - Cellulosic biofuel: 60% - Advanced biofuel: 50% - Total renewable fuel: 20%	At least 60% lower carbon footprint than their fossil fuel alternatives GHG, 83.8 gCO ₂ eq/MJ

2. Data and Methods

This analysis examines the role of sustainability criteria in renewable fuel programs to ensure that biofuel standards are used in ways that guarantee real carbon savings and protect biodiversity with the goal of evaluating Korea's RFS program [29]. The RFS program of the US and the RTFO program of the UK are used as the basis for comparison for the following reasons. When Korea's renewable fuels program was first developed, the US's RFS served as the benchmark for several key aspects of what became Korea's RFS, including program structure, blending plans, obligated parties, and compliance [30]. Due to the established similarities between the two programs, comparison to the US's RFS is informative. At the same time, however, the UK serves as a much better model for Korea's energy environment with respect to a lack of abundant domestic energy sources and similarity of feedstocks for biodiesel, including UCO, tallow, palm oil, and soybean oil [31]. In order to arrive at a more accurate measure of the GHG reduction associated with Korea's RFS, the carbon savings and sustainability of specific fuel types will also be considered in evaluating Korea's RFS program.

2.1. Sustainability of Biodiesel in the US

The US government is trying to expand the nation's renewable fuel sector by reducing both GHG and reliance on imported oil. The State and Alternative Fuel Provider Fleet Program of the Department of Energy and the RFS of the Environmental Protection Agency (EPA) are the main programs to reduce GHG; both require covered fleets to use alternative fuels, including biofuels [32]. However, these programs not only require fleets to use biofuels but also mandate the use of biofuels that meet their sustainability criteria. In 2010, the EPA established new fuel pathways to qualify for RFS, consisting of a specific combination of three components: Feedstock, production process, and fuel type. Assessment of lifecycle GHG emissions is necessary to determine which fuel pathways can qualify [33]. The EPA's lifecycle GHG analyses take into account all of the energy used during the entire feedstock-to-fuel lifecycle from planting to final processing, as well as DLUC, ILUC, and emissions from storage and handling of the refined fuel (see Figure 5).

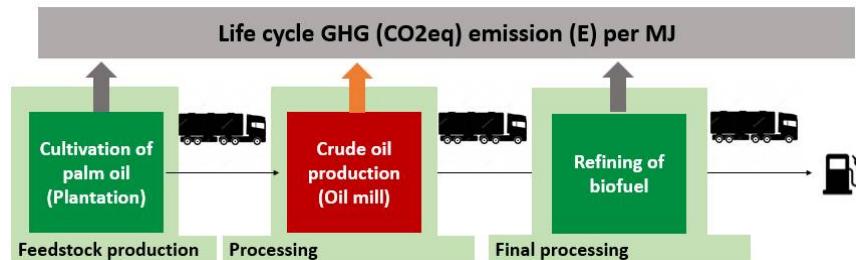

Figure 5. Life cycle greenhouse gas emissions (GHG) of palm oil-based biofuel [34].

To qualify under RFS, fuels must reduce GHG emissions compared to a 2005 petroleum baseline. As shown in Figure 6, the EPA has approved fuel pathways under the RFS program for renewable, advanced, biodiesel, and cellulosic fuels. As Figure 6 shows, advanced and biodiesel fuels must achieve a GHG reduction of 50% compared to petroleum-based fuels in order to qualify.

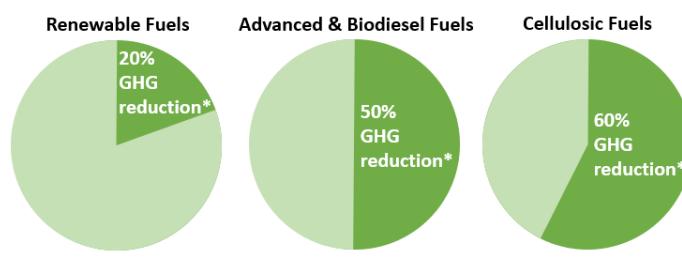

Figure 6. Lifecycle GHG emissions [35].

Table 2 shows the lifecycle analysis of GHG resulting from various feedstocks [36]. The EPA's analysis found that biodiesel and renewable diesel produced from palm oil have estimated lifecycle GHG emission reductions of 17% and 11%, respectively, compared to the baseline petroleum diesel fuel they replace. These biofuels, therefore, fail to meet the minimum GHG emissions reduction threshold of 50% set by the Energy Independence and Security Act (EISA) for renewable fuel made in facilities constructed after December 19, 2007 [37,38].

Table 2. Lifecycle analysis GHG results for select pathways (kg CO₂eq/mmBtu) [36].

Feedstock	Production Process	Ag. Impact	LUC	Feedstock Transport	Fuel Production	Fuel Dist. & Use	Net Emissions	% Reduction
Algal oil	Transesterification (Open pond, mid)	0.0	0.0	0.0	31.5	1.5	33.0	66%
	Transesterification (PBR, mid)	0.0	0.0	0.0	26.3	1.5	27.8	71%
Canola oil	Transesterification	8.2	33.9	1.6	2.9	1.5	48.1	50%
Cellulose from corn stover	Fischer-Tropsch process	11.6	-11.2	1.2	5.4	2.0	9.0	91%
Palm oil	Transesterification	4.8	46.1	1.3	25.1	3.4	80.7	17%
	Hydrotreating	4.8	46.8	2.0	30.9	2.2	86.7	11%
Soy bean oil	Transesterification	-8.8	33.6	2.7	13.2	1.5	42.2	57%
Switch-grass	Fischer-Tropsch process	6.5	13.1	1.6	5.4	2.0	28.6	71%
Yellow grease	Transesterification	0.0	0.0	2.7	9.6	1.5	13.8	86%
Petroleum	Refining	0.0	0.0	0.0	18.0	79.0	97.0	0%

Analysis by the EPA highlights a number of key factors that contribute to the lifecycle emissions estimates for biofuels based on palm oil. For example, a process of palm oil production causes wastewater effluent that creates methane (CH₄), a GHG with a high global warming potential. Expanding the expected palm plantations onto land having carbon-rich peat soils is another important factor, as destruction of carbon-rich soils causes greater emissions of GHGs to the atmosphere [37].

Figure 7, above, shows the lifecycle GHG of palm oil-based biodiesel, as calculated using GREET 2017. Palm oil-based biodiesel's GHG emission reduction from the GREET Excel version shown in Table 3 below is approximately 24.2 kg CO₂eq/mmBtu (=10,723 + 13,468, the bottom line of Table 3), in which LUC was not included. If the LUC 46.1 kg CO₂eq/mmBtu from Table 2 is included, the total GHG will be about 70.3 kg CO₂eq/mmBtu. This also cannot meet the minimum GHG emission reduction threshold of 50%. GREET does not include LUC due to controversy on how to calculate it.

According to the Argonne National Laboratory, the value 24.2 kg CO₂eq/mmBtu for palm oil-based biodiesel's GHG emission is based on the assumption that the CH₄ from palm oil mill effluent is captured. However, due to the high capture cost, some CH₄ is not collected and is instead discharged into the environment from production sites. Therefore, 24.2 kg CO₂eq/mmBtu is the minimum value, and palm oil-based biodiesel's GHG emission value would increase when uncaptured CH₄ and LUC are considered.

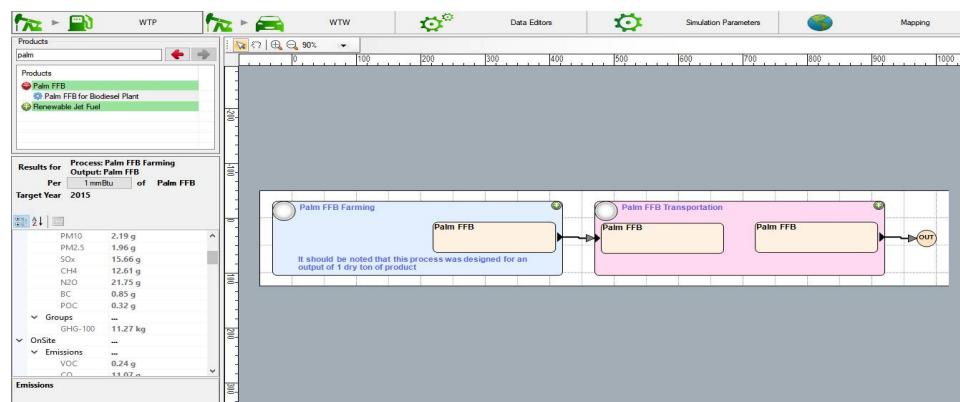

Figure 7. Palm fresh fruit bunches (FFB) lifecycle GHG from GREET 2017 [39].

Table 3. Palm oil-based biodiesel emissions (g CO₂eq/mmBtu).

Emissions	Feedstock	Fuel
Loss factor		1.000
Unit	per mmBtu	per mmBtu
Total energy	73,005	243,951
Fossil fuels	72,341	184,803
Coal	1,802	10,100
Natural gas	43,444	127,123
Petroleum	27,095	47,579
Water consumption	3,575	4,651
VOC	5,904	5,430
CO	12,704	11,621
NOx	33,699	68,841
PM10	2,004	5,230
PM2.5	1,754	4,664
SOx	14,471	39,803
BC	0,705	0,802
OC	0,302	1,757
CH ₄	12,373	29,676
N ₂ O	19,659	0,170
CO ₂	5,104	12,498
CO ₂ (w/ C in VOC & CO)	5,143	12,533
GHGs	10,723	13,468

2.2. Sustainability of Biodiesel in the UK

As mentioned earlier, the EU, including the UK, faces the dilemma of how to expand the role of biofuel as part of their overall energy portfolio while also considering the sustainability of feedstock obtained from land with a high biodiversity value. As a result of this issue, the EU keeps tightening the rules for use of biofuel, including the recent ban of palm oil. While the UK has not officially announced its position on the Indonesian palm oil trade dispute [40], recently, private companies in the UK have moved in advance to ban palm oil. For example, Iceland Foods, a major UK grocery store chain, has announced that it would stop using palm oil in its own-brand food products [41], and despite the lack of a clear official stance on palm oil, since 2015, no biodiesel based on palm oil has been consumed in the UK [42].

The UK's Renewables Obligation (RO) and the RTFO are based on the EU's RED, which establishes an overall policy for the production and promotion of energy from renewable sources in the EU. Under the RED, operators using bioliquids in the EU, as well as the in the UK, must meet specified carbon intensity (CI) sustainability criteria to be eligible for support under national schemes [43,44].

As shown in Table 4, according to the RO sustainability criteria, beginning 1 January 2018, the percentage saving required against the fossil fuel comparator will be determined by whether the bioliquid was produced in a facility that began bioliquid production before 1 January 2017. If so, the saving required against the fossil fuel comparator will be 50%. If not, then the saving required will be 60% [43].

Table 4. GHG thresholds for bioliquids [43].

Before 1 January 2017	1 January ~31 December 2017	On or after 1 January 2018	
		For bioliquids produced in an installation that started producing bioliquid before 1 January 2017	For bioliquids not produced in an installation that started producing bioliquid before 1 January 2017
GHG emission threshold	35%	50%	50%
			60%

As the RED's Directive 2009/28/EC for biofuels describes, the fossil fuel comparator should be the latest available actual average emissions from the fossil part of petrol and diesel consumed in the community, as reported under Directive 98/70/EC. If no such data is available, the value used should be 83.8 g CO₂eq/MJ [44]. The RTFO guidance also provides the same fossil fuel comparator value.

The RTFO guidance, as shown in Table 5, provides each biodiesel's default CI. Palm oil biodiesel's CI is 72 kgCO₂eq/mmBtu (68 gCO₂eq/MJ), approximately the same value as the EPA's 81 kgCO₂eq/mmBtu. In the UK as in the US, palm oil-based biodiesel's GHG savings of 19% cannot meet the 50% threshold.

Table 5. Bioliquid default carbon intensities and disaggregated default values [28].

Bioliquid Production Pathway	Default CI [gCO ₂ eq/MJ]	Disaggregated Default Values [gCO ₂ eq/MJ]			GHG Saving
		Cultivation	Processing	Transport & Distribution	
Palm oil biodiesel (process not specified)	68	14	49	5	19%
Rape seed biodiesel	52	29	22	1	38%
Soybean biodiesel	58	19	26	13	31%
Waste vegetable or animal biodiesel	14	0	13	1	83%

Besides CI, the RTFO administrator, the Secretary of State for Transport, requires biofuel suppliers to submit verified data regarding the sustainability of the biofuel they supply. Most of the required information and criteria for sustainability, consisting of feedstock cultivation region, biodiversity, carbon stock and peat-lands, and cross compliance, are connected with the EU's RED.

Cultivation region: Obligors of the RTFO must demonstrate that feedstocks were sourced from a region where typical GHG emissions associated with their cultivation can be expected to be equal to or lower than the RED GHG default values (Appendix A). Regions are defined at the Nomenclature of Territorial Units for Statistics (NUTS2) level [28].

Biodiversity: To meet biodiversity criteria, as per land use restrictions of the RED, biofuels may not be made from raw material coming from land with a high biodiversity value at any point during or since January 2008 [28]. Here, high biodiversity value means primary forest and other wooded land of native species, where there is no clearly visible indication of human activity, and the ecological processes are not significantly disturbed (Appendix B). The EU also adopted a regulation for the definition of highly biodiverse grasslands, namely grassland that would remain grassland in the absence of human intervention, on 8 December 2014, which applies from 1 October 2015.

Carbon stock and peat-lands: Biofuels may not be made from raw materials obtained from land with high carbon stock or land that was undrained peat-land, like wetlands and forests, in January 2008, unless strict criteria are met (Appendix B).

Cross compliance: Biofuel feedstocks grown in the European community must be cultivated according to the European Commission's "Cross Compliance" requirements and must meet the minimum requirements for good agricultural and environmental conditions (Appendix C).

The RTFO program, like RED, also tries to promote the use of waste and residue feedstocks by double-counting biofuel produced from wastes, residues, non-food cellulosic material, and lignocellulosic material toward suppliers' obligations. This means that one liter of biofuel produced from wastes/residues will receive two Renewable Transport Fuel Certificates (RTFC).

Table 6 below indicates the carbon and sustainability data that fuel suppliers must report to the RTFO administrator. This reporting is crucial to proving compliance with the RED sustainability criteria and earning RFTCs.

Table 6. Illustrative carbon and sustainability reporting data [28].

General Information			Country of Origin Information			Land Use	CI	Indirective RED Compliance			
Consign- ment No.	Fuel type	Biofuel feedstock	Production process	Country of origin	NUTS2 compliance	Land Use on 1 Jan. 2008	Carbon intensity	GHG	Bio- diversity	C- stock	RED compliance
01	Bio- ethanol	Wheat	Unknown	UK	Y	Cropland- protected	70	N	Y	Y	N
02	Bio- ethanol	Wheat	Natural gas CHP	Croatia	HRO4	Cropland- protected	44	N	Y	Y	N
03	Bio- ethanol	Bio- gasses	-	Brazil	N/A	-	35	Y	N	N	N
04	Bio- diesel	Oilseed rape	-	UK	Y	Cropland- non-protected	52	N	Y	Y	N
05	Bio- diesel	UCO	-	Waste/non- ag. residue	N/A	Waste/non- ag. residue	14	Y	Y	Y	Y
06	Biogas	Dry manure	-	Waste/non- ag. residue	N/A	Waste/non- ag. residue	15	Y	Y	Y	Y

For example, the feedstock in consignment 04 above, was cultivated in a compliant NUTS2 region, had no land-use change, and the land use on 1 January 2008 was reported as cropland-nonprotected. The carbon default of 52 gCO₂eq/MJ can be reported. However, it does not meet the GHG saving threshold of 50% introduced from 1 January 2017. It, therefore, does not meet the GHG saving and overall scores an 'N' for RED compliance, as it does not meet the GHG criteria.

In Table 5, palm oil biodiesel's (process not specified) GHG savings of 19% cannot meet the threshold of 50%. However, if biodiesel is produced from palm oil at a production facility that captures CH₄, as on the bottom row of Table 7, it can meet the threshold. As Table 7 shows, the CI of biodiesel (Methyl ester) from palm is 37 gCO₂eq/MJ, a 56% carbon savings, which can meet the threshold of 50%.

Table 7. Process default values [28]

Fuel	Feedstock	Process Characteristic	CI (gCO ₂ eq/MJ)	Carbon saving (%)
Bioethanol, ETBE, TAME	Corn (produced within the EU)	Natural gas a process fuel in CHP plant	43	49
		Lignite as process fuel in CHP plant	70	16
	Wheat	Natural gas as process fuel in conventional boiler	55	34
		Natural gas as process fuel in CHP plant	44	47
		Straw as process fuel in CHP plant	26	69
Biodiesel (Methyl ester)	Palm	Methane capture at oil mill	37	56
Biodiesel (HVO)	Palm	Methane capture at oil mill	29	65

Figure 8 shows the UK and Ireland carbon calculator, which is used by fuel suppliers and the Department of Transportation to reduce the potential for errors during calculation of CI. This software shows (a fuel lifecycle CI for Methyl ester biodiesel of 36.9 gCO₂eq/MJ, almost exactly the same as from Table 7.

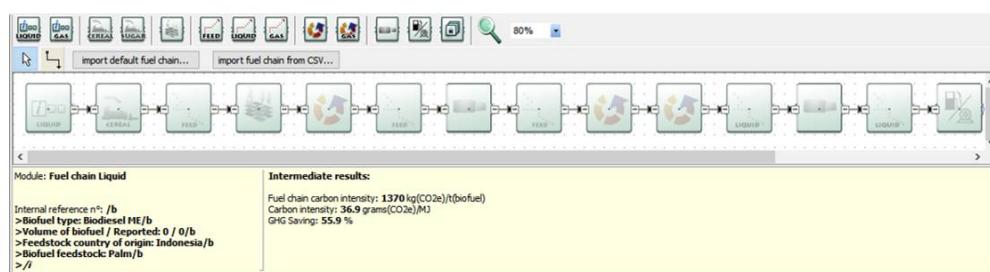

Figure 8. Illustrative carbon and sustainability reporting data.

To expand the qualified yearly biofuel volume, the UK mandates obligators to supply biofuel and requires that they also meet the specified sustainability criteria. In April 2018, it was announced that the RTFO biofuel volume target would increase to 9.75% in 2020 and 12.4% in 2032 from the current 4.75%. An initial cap of 4% crop-based biofuel is set for 2018. The cap will be reduced annually from 2021 to reach 3% in 2026 and 2% in 2032 [45].

2.3. Sustainability of Biodiesel in Korea

The RFS program of Korea does not have specified source-based carbon savings and sustainability criteria for biofuels, unlike the US and UK. In other words, if a supplier in Korea provides 1000 L of biodiesel to a pump, calculated GHGs corresponding to that volume will be reduced regardless where the biodiesel came from and how much GHG will be emitted during the fuel's lifecycle. This aspect of the RFS program in Korea therefore does not follow the US and UK model of considering the overall sustainability of the biodiesel lifecycle.

Table 8 shows the biodiesel feedstocks used to manufacture biodiesel for domestic use in Korea for selected years from 2006 to 2015 [46]. Domestic UCO and imported PFAD have been the main feedstocks since 2010 and accounted for approximately 83% of Korea's biodiesel in 2015. Biodiesel production companies have collected used cooking oil as a feedstock and imported PFAD to replace palm oil since 2010 [18].

Table 8. Raw material proportion of biodiesel in Korea, 10³ ton [46].

Feedstock		2006	2008	2010	2012	2014	2015
Domestic	UCO	16	57	78	121	144.3	147.1
	Tallow	-	-	-	-	14.9	27.4
	Others	0.4	0.1	-	-	5.3	4.5
	Subtotal	16.4	57.1	78	121	164.5	179.0
Imported	Soybean	46	69	80	19	3.5	2.8
	Palm fatty acid distillate (PFAD)	-	30	102	136	154.8	169.6
	Palm oil	-	34	69	62	21.4	28.3
	UCO	-	0.1	25	38	34.8	34.5
	Tallow (Beef)	-	-	-	-	-	-
	Others	-	16	4	9	5.2	7.1
	Subtotal	46	149.1	280	264	219.7	242.3
	Total	62.4	149.1	280	385	384.2	421.5
Localization rate		26.3	27.7	21.8	31.4	42.8	42.5

2.4. Method

GHG emissions for biodiesel from two of the four feedstocks that form the basis for most of Korea's biodiesel (tallow, palm oil) were calculated using the Argonne National Laboratory's Greenhouse gases, Regulated Emissions, and Energy use in Transportation (GREET) model suite (2014 version), which shows the total GHG emissions from biofuel cultivation to biofuel pump. Subsequently, the GHG emissions for UCO, tallow, palm oil, and PFAD (the four feedstocks most used in Korea) were calculated using the UK and Ireland carbon calculator, and the values for tallow and palm oil found using the UK and Ireland calculator were compared to the GREET values to confirm the accuracy of the results (GREET does not have UCO and PFAD). Using the results from the UK and Ireland calculator and the volume of each feedstock used in biodiesel for domestic consumption in 2015 (see Table 8), it was possible to calculate the total GHG resulting from the biodiesel portion of the transportation sector. That calculated emission was then compared to the total GHG from the transportation sector calculated using the emission factors from 2006 IPCC Guidelines for National Greenhouse Gas Inventories and treating biodiesel as carbon neutral.

3. Results

When the UK and Ireland carbon calculator was used to calculate GHG emissions for biodiesel based on the amounts of four feedstocks, UCO, tallow, palm oil, and PFAD, used in Korea in 2015, the total GHG for biodiesel were found to be $370.2 \text{ } 10^3 \text{tCO}_2\text{eq}$. Table 9 shows the calculated values. In Table 9, the CI unit ($\text{gCO}_2\text{eq/MJ}$) reported by the UK and Ireland carbon calculator was converted to ($\text{kgCO}_2\text{eq/t}$) (biofuel) because domestic biodiesel feedstocks were reported in tons.

Table 9. GHG emissions of biodiesel usage in Korea in 2015 [28, 46].

	10^3ton	Percent	CI ($\text{gCO}_2\text{eq/MJ}$)	CI ($\text{kgCO}_2\text{eq/t(Biofuel)}$)	GHG emissions ($10^3 \text{tCO}_2\text{eq}$)
UCO	181.6	43%	14	471	85.5
Tallow	27.4	7%	14	471	12.9
PFAD	169.6	40%	37	1370	232.4
Palm oil	28.3	7%	37	1370	39.5
Others	14.4	3%	-	-	-
Total	421.5	100%			370.2

Table 10 shows the quantities of diesel and biodiesel used by Korea's transportation sector in 2015, as well as the GHG emissions when biodiesel is assumed to be carbon neutral. (The diesel GHG, $53,898.5 \text{ } 10^3 \text{tCO}_2\text{eq}$, was calculated using the emission factors from 2006 IPCC Guidelines for National Greenhouse Gas Inventories.) Table 11 shows the quantities of diesel and biodiesel used and the GHG using the calculated GHG for biodiesel. The biodiesel quantity shown in Tables 10 and 11, $441.0 \text{ } 10^3 \text{TOE}$, is slightly different from the total quantity of biodiesel, $421.5 \text{ } 10^3 \text{TOE}$, shown in Table 9 because these tables were created based on statistics from different sources. The National Greenhouse Gas Inventory Report of Korea [47] provided the total quantity of biodiesel used, $441.0 \text{ } 10^3 \text{TOE}$. The quantities of individual feedstocks shown in Tables 8 and 9 were from the Bioenergy Association. Differences in quantities shown derive from differences in the time and method of investigation.

Table 10. Korea's transportation sector diesel and biodiesel quantity used and GHG emissions in 2015, assuming biodiesel is carbon neutral [47].

	Energy Used (10^3TOE)	Total GHG Emission ($10^3 \text{tCO}_2\text{eq}$)
Diesel	17,358.0	53,898.5
Biodiesel	441.0	-
Total	17,799.0	53,898.5

Table 11. Korea's transportation sector diesel and biodiesel quantity used and GHG emissions in 2015, including calculated GHG for biodiesel [47].

	Energy Used (10^3TOE)	% of Total	Total GHG Emission ($10^3 \text{tCO}_2\text{eq}$)	% of Total
Diesel	17,358.0	97.5	53,898.5	99.3
Biodiesel	441.0	2.5	370.2	0.7
Total	17,799.0	100.0	54,268.7	100.0

As Table 11 shows, at B2.5, the RFS blend ratio in 2015, GHG emissions from biodiesel represent 0.7% of total diesel and biodiesel GHG.

To calculate the reduction in GHG resulting from biodiesel, Table 12 shows the predicted GHG emissions in a no-biodiesel (100% diesel) scenario. As Table 12 shows, in a no-biodiesel scenario, GHG is $55,267.9 \text{ } 10^3 \text{tCO}_2\text{eq}$, a net increase of $999.2 \text{ } 10^3 \text{tCO}_2\text{eq}$

Table 12. Predicted 2015 GHG emissions in a no-biodiesel scenario.

	No-Biodiesel Scenario		GHG Emission ($10^3 \text{tCO}_2\text{eq}$)	
	10^3 TOE	Amount inc/dec	GHG Total	Amount inc/dec
Diesel	17,799.0	+441.0	55,267.9	+1,369.4
Biodiesel	0.0	-441.0	0.0	-370.2
Net increase in GHG in a no-biodiesel scenario				+999.2

4. Discussion

In the transportation sector, the Korean government's long-term GHG reduction goals include developing EV infrastructure and promoting eco-friendly public transportation; but as a transitional phase, the RFS is a significant component of the current GHG mitigation plan [48]. As this research shows, biodiesel does promote significant carbon savings by comparison to petroleum-based diesel; however, biodiesel is not carbon neutral, and the difference in carbon savings based on different feedstocks is quite significant. Moreover, long-term soil degradation, loss of biodiversity, and excessive water use associated with feedstocks such as palm oil create environmental costs whose future effects cannot be fully anticipated and that are in addition to the environmental impact of GHG emissions. Therefore, Korea's RFS program could be improved by including sustainability criteria like the ones included in the US's RFS and the UK's RTFO that do not regard biofuels as inherently carbon neutral, but instead consider the GHG costs of DLUC and ILUC, as well as lifecycle GHG emissions.

PFAD, accounting for 40% of Korea's biodiesel feedstock in 2015, is also questionable in terms of its sustainability. In Norway and Sweden, PFAD was not categorized as a coproduct but as a residue. Because the primary lifecycle environmental cost of manufacturing a product is associated with products and co-products but not residues, a residue is understood to carry a lower environmental cost [49]. Therefore, when PFAD is defined as a residue, it appears to be superior to palm oil in sustainability. However, when PFAD is reclassified as a coproduct, its sustainability is no better than palm oil's, rendering it unsuitable as a biofuel feedstock. In addition, palm oil, like petroleum, is a raw material that must be imported and therefore does not contribute to Korea's overall energy security. Consequently, the inclusion of PFAD is a significant weakness of Korea's RFS program. In order to promote energy security while reducing carbon cost, Korea should explore the potential of domestic feedstocks such as microalgae and food and agricultural waste.

UCO, which provided the feedstock for 35% of Korea's biodiesel in 2015, represents an increasing percentage of Korea's biodiesel, and with one of the lowest CIs of the biodiesels at 14 gCO₂eq/MJ, yields an 83% carbon saving [28]. The Korean government plans to increase the role of UCO in Korea's biodiesel portfolio. However, UCO has already met its limited domestic supply potential, so increasing the share of biodiesel feedstock from UCO means, again, relying on an imported energy product. At this time, the Korean government is promoting development of technologies to produce biodiesel from tallow and waste oil, as shown Table 13, which, if successful, would be preferable alternatives to imported UCO.

Table 13. Ranking of supply potential of biodiesel feedstocks [18].

Feedstock	The Amount that Can Be Secured	Feedstock Cost	Unit Cost of Production	Ranking Supply Potential
Palm and PFAD	★★★★★	★★★★★	★★★★★	1
Domestic UCO	★★★★	★★★★★	★★★★★	2
Domestic tallow	★★★	★★★★★	★★★★★	3
Domestic waste oil	★★	★★★★★	★★	4
Domestic rape oil	★★★	★	★★★★★	5
Domestic Microalgae	★	★	★	6

In developing the sustainability components of the RFS program, the Korean government needs to review the international certification program Roundtable on Sustainable Biofuels (RSB), as well as other countries' policies. By applying the international standard, Korea can avoid risks associated with adopting a policy developed for another country with a different energy profile.

Finally, with respect to the development of EV technology and the environmental cost of clean energy, Tessum et al. found that EVs charged from the current grid average did not have lower net environmental impact than combustion engine vehicles [50]. The current grid average is limited in its sustainability by each country's major power suppliers, which means that the overall environmental benefit of EVs is a factor of the overall power industry. Therefore, the immediate GHG

mitigation impact of EVs will be low in countries with power grids more heavily dependent on coal and natural gas and higher in countries with more wind, solar, and other renewable energy sources. Even so, the price of EVs is still too expensive for most consumers. However, as EV and grid technology develops, the EV sticker price will go down, reducing the economic burden on consumers of selecting the lower-emission option and removing the barrier of cost that may prevent some consumers from making the switch. Likewise, most of the current biofuels are not perfectly environmentally friendly energy sources, and some feedstocks have significant environmental costs. In addition, the per-litre cost of biofuel blended fuels is higher for consumers, an economic burden that should be taken into account as the RFS program is adapted to meet ongoing GHG reduction goals.

5. Conclusions

In April 2018, the EU tightened its rules for biofuels by banning palm oil. The RFS is the one of Korea's primary mechanisms for reducing GHG emission in the transportation sector in order to implement the INDC plan. Korea, which emitted 585 million tCO₂ in 2015, ranking seventh in total emissions by country, does not have carbon saving and sustainability criteria and instead treats all biodiesel as carbon neutral. However, this study found that when the UK and Ireland carbon calculator was used to calculate GHG emissions for biodiesel used in Korea in 2015, the total GHG for biodiesel was 370.2 10³tCO₂eq. As the RFS is the main program for mitigating CO₂ emissions from the transportation sector, the RFS should take into account the feedstock's lifecycle GHG. Therefore, the introduction of new criteria into the RFS program should be considered urgent. Development of environmentally friendly vehicles is not sufficient to mitigate GHG emissions. Much greater potential impact can be expected from a more aggressive RFS program that includes a consideration of LCA.

Rules for calculating the greenhouse gas impact of biofuels, bioliquids and their fossil fuel comparators

D. Disaggregated default values for biofuels and bioliquids

Table A1. Total for cultivation, procession, transport and distribution.

Biofuel and bioliquid production pathway	Typical greenhouse gas emissions (gCO ₂ eq/MJ)	Default greenhouse gas emissions (gCO ₂ eq/MJ)
Sugar beet ethanol	33	40
Wheat ethanol (process fuel not specified)	57	70
Wheat ethanol (lignite as process fuel in CHP plant)	57	70
Wheat ethanol (natural gas as process fuel in conventional boiler)	46	55
Wheat ethanol (natural gas as process fuel in CHP plant)	39	44
Wheat ethanol (straw as process fuel in CHP plant)	26	26
Corn (maize) ethanol, Community produced (natural gas as process fuel in CHP plant)	37	43
Sugar cane ethanol	24	24
The part from renewable sources of ETBE	Equal to that of the ethanol production pathway used	
The part from renewable sources of TAME	Equal to that of the ethanol production pathway used	
Rape seed biodiesel	46	52
Sunflower biodiesel	35	41
Soybean biodiesel	50	58
Palm oil biodiesel (process not specified)	54	68
Palm oil biodiesel (process with methane capture at oil mill)	32	37
Waste vegetable or animal oil biodiesel	10	14
Hydrotreated vegetable oil from rape seed	41	44
Hydrotreated vegetable oil from sunflower	29	32
Hydrotreated vegetable oil from palm oil (process not specified)	50	62
Hydrotreated vegetable oil from palm oil (process with methane capture at oil mill)	27	29
Pure vegetable oil from rape seed	35	36
Biogas from municipal organic waste as compressed natural gas	17	26
Biogas from wet manure as CNG	13	16
Biogas from dry manure as CNG	12	15

Appendix B

Directive 2009/28/EC of the European Parliament and of the council of 23 April 2009, Article 17

Sustainability criteria for biofuels and bioliquids

1. Irrespective of whether the raw materials were cultivated inside or outside the territory of the Community, energy from biofuels and bioliquids shall be taken into account for the purposes referred to in points (a), (b) and (c) only if they fulfil the sustainability criteria set out in paragraphs 2 to 6:

- (a) Measuring compliance with the requirements of this Directive concerning national targets;
- (b) Measuring compliance with renewable energy obligations;
- (c) Eligibility for financial support for the consumption of biofuels and bioliquids.

However, biofuels and bioliquids produced from waste and residues, other than agricultural, aquaculture, fisheries and forestry residues, need only fulfil the sustainability criteria set out in paragraph 2 in order to be taken into account for the purposes referred to in points (a), (b) and (c).

2. The greenhouse gas emission saving from the use of biofuels and bioliquids taken into account for the purposes referred to in points (a), (b) and (c) of paragraph 1 shall be at least 35 %. With effect from 1 January 2017, the greenhouse gas emission saving from the use of biofuels and bioliquids taken into account for the purposes referred to in points (a), (b) and (c) of paragraph 1 shall be at least 50 %. From 1 January 2018 that greenhouse gas emission saving shall be at least 60 % for biofuels and bioliquids produced in installations in which production started on or after 1 January 2017. The greenhouse gas emission saving from the use of biofuels and bioliquids shall be calculated in accordance with Article 19 (1). In the case of biofuels and bioliquids produced by installations that were in operation on 23 January 2008, the first subparagraph shall apply from 1 April 2013.

3. Biofuels and bioliquids taken into account for the purposes referred to in points (a), (b) and (c) of paragraph 1 shall not be made from raw material obtained from land with high biodiversity value, namely land that had one of the following statuses in or after January 2008, whether or not the land continues to have that status:

- (a) Primary forest and other wooded land, namely forest and other wooded land of native species, where there is no clearly visible indication of human activity and the ecological processes are not significantly disturbed;
- (b) Areas designated:

- (i) By law or by the relevant competent authority for nature protection purposes; or
- (ii) For the protection of rare, threatened or endangered ecosystems or species recognized by international agreements or included in lists drawn up by intergovernmental organizations or the International Union for the Conservation of Nature, subject to their recognition in accordance with the second subparagraph of Article 18(4); unless evidence is provided that the production of that raw material did not interfere with those nature protection purposes;

- (c) Highly biodiverse grassland that is:

- (i) Natural, namely grassland that would remain grassland in the absence of human intervention and which maintains the natural species composition and ecological characteristics and processes; or
- (ii) Non-natural, namely grassland that would cease to be grassland in the absence of human intervention and which is species-rich and not degraded, unless evidence is provided that the harvesting of the raw material is necessary to preserve its grassland status.

The Commission shall establish the criteria and geographic ranges to determine which grassland shall be covered by point (c) of the first subparagraph. Those measures, designed to amend nonessential elements of this Directive, by supplementing it shall be adopted in accordance with the regulatory procedure with scrutiny referred to in Article 25(4).

4. Biofuels and bioliquids taken into account for the purposes referred to in points (a), (b) and (c) of paragraph 1 shall not be made from raw material obtained from land with high carbon stock, namely land that had one of the following statuses in January 2008 and no longer has that status:
 - (a) Wetlands, namely land that is covered with or saturated by water permanently or for a significant part of the year;
 - (b) Continuously forested areas, namely land spanning more than one hectare with trees higher than five meters and a canopy cover of more than 30%, or trees able to reach those thresholds in situ;
 - (c) Land spanning more than one hectare with trees higher than five meters and a canopy cover of between 10% and 30%, or trees able to reach those thresholds in situ, unless evidence is provided that the carbon stock of the area before and after conversion is such that, when the methodology laid down in part C of Annex V is applied, the conditions laid down in paragraph 2 of this Article would be fulfilled.

The provisions of this paragraph shall not apply if, at the time the raw material was obtained, the land had the same status as it had in January 2008.

Appendix C

Council Regulation (EC) No 73/2009 of 19 January 2009, Annex III

Table A2. Good agricultural and environmental condition.

Issue	Compulsory Standards	Optional Standards
Soil erosion: Protect soil through appropriate measures	Minimum soil cover Minimum land management reflecting site-specific conditions	Retain terraces
Soil organic matter: Maintain soil organic matter levels through appropriate practices	Arable stubble management	Standards for crop rotations
Soil structure: Maintain soil structure through appropriate measures		Appropriate machinery use
Minimum level of maintenance: Ensure a minimum level of maintenance and avoid the deterioration of habitats	Retention of landscape features, including, where appropriate, hedges, ponds, ditches trees in line, in group Avoiding the encroachment of unwanted veg Protection of permanent pasture	Minimum livestock stocking rates or/and appropriate regimes Establishment and/or retention of habitats Prohibition of the grubbing up of olive trees Maintenance of olive groves and vines in good vegetative condition
Protection and management of water: Protect water against pollution and run-off, and manage the use of water	Establishment of buffer strips along water courses (1) Where use of water for irrigation is subject to authorization, compliance with authorization procedures	

(1) Note: The GAEC buffer strips must respect, both within and outside vulnerable zones designated pursuant to Article 3(2) of Directive 91/676/EEC, at least the requirements relating to the conditions for land application of fertilizer near water courses, referred to in point A.4 of Annex II to Directive 91/676/EEC to be applied in accordance with the action programs of Member States established under Article 5(4) of Directive 91/676/EEC.
