Abstract—In this paper, at first, a color image of a car is taken. Then the image is transformed into a grayscale image. After that, the motion blurring effect is applied to that image according to the image degradation model described in equation 3. The blurring effect can be controlled by a and b components of the model. Then random noise is added in the image via Matlab programming. Many methods can restore the noisy and motion blurred image; particularly in this paper Inverse filtering as well as Wiener filtering are implemented for the restoration purpose. Consequently, both motion blurred and noisy motion blurred images are restored via Inverse filtering as well as Wiener filtering techniques and the comparison is made among them.

Keywords—Color image, grayscale image, motion blurring, random noise, inverse filtering, Wiener filtering, restoration of an image.

I. INTRODUCTION

In digital image processing, image restoration is an essential approach used for the retrieval of uncorrupted, original image from the blurred and noisy image [1, 2] because of motion blur, noise, etc. caused by environmental effects [3] and camera misfocus. Image blur may occur for many reasons such as motion blur which is due to the sluggish camera shutter speed comparative to the instantaneous motion of the targeted object [4]. The image also may subject to several forms of noises such as Poisson noise, Gaussian noise, etc. Poisson noise is controlled by signal and it is associated with the low light sources owing to photon counting statistic [4]. In contrast, the reason of Gaussian noise is because of electronic components and broadcast transmission effects [4]. In short, the term image restoration is an inverse process [5] by which the uncorrupted, original image can be recovered from the degraded form of the actual image [6]. There are many useful applications of digital image restoration in several fields including the area of astronomical imaging, medical imaging, media and filmography, security and surveillance, forensic science, image and video coding, centralized aviation assessment procedures [7], uniformly blurred television pictures restoration [8], etc. Several algorithmic techniques such as Artificial Neural Network [9], Convolutional neural Network [10], and K-nearest Neighbors [11] can also be applied in image processing techniques such as segmentation, thresholding and filtering. The technique used in image restoration is known as filtering which suppresses or removes unwanted components or features from the images. The most popular filtering techniques are used in image restoration in recent times are inverse filtering and Wiener filtering [12].

Inverse filter is a handy technique for image restoration if a proper degradation function can be modeled for the corrupted image. The performance of the inverse filter is quite right when the noise does not corrupt images, but in the presence of noise in the images, performance degrades significantly as high pass inverse filtration cannot eliminate noise properly because noise tends to be high frequency.

Wiener filter is incorporated with low pass filter together with high pass filter; as a result, it works actively in the existence of additive noise within the image. It performs deconvolution operation (high pass filtering) to invert motion blurring and also perform compression operation i.e. (low pass filtering) to eliminate the additive noise. Furthermore, in the process of inverting motion blurring and noise elimination, Wiener filter diminishes the overall mean square inaccuracy between the original and the output image of the filtration.

In this paper, the implementation of inverse filtering and Wiener filtering are analyzed for image restoration. Inverse filtering is applied into a motion blurred car image at first, and then wiener filtering is also used to the same image. After that, inverse and Wiener filtering are performed on the same motion blurred car image with additive noise. Finally, the comparison is made between inverse and Wiener filtering regarding their performances in restoring motion blurred images with and without additive noise.

II. LITERATURE REVIEW

Over the past two decades, the technique of image processing has taken its place into every aspect of today's technological society. In digital image processing, there are a variety of essential steps involved such as image enhancement, pre-processing of images, image segmentation, image restoration and reconstruction of images etc. Among them, image restoration plays a vital role in today's world. It has several fields of applications in the areas of astronomy, remote sensing, microscopy, medical imaging, satellite imaging, molecular spectroscopy, law enforcement, and digital media restoration etc. Image restoration is very challenging as there is a lot of interference and noise in the environment like Gaussian noise, multiplicative noise, and impulse noise etc, inclusive of the camera such as wide angle lens, long exposure times, wind speed and degradation, blurring such as uniform blur, atmospheric blur, motion blur, and Gaussian blur etc. However, there are various methods of image restoration in the domain of image processing, for instance, Median filter, Wiener filtering, inverse filtering, Harmonic mean filter, Arithmetic mean filter, Max filter, and Maximum Likelihood (ML) method etc. Among these restoration methods, Wiener and inverse filtering method is the
Image restoration is a restoring or recovering process of a degraded image by utilizing some prior knowledge of degradation method which has degraded the image. So the image restoration process involves the estimation of the deteriorated model as well as the relevance of the inverse filtering to restore or retrieve the original image [24]. Although the reconstructed image may not be the exact form of the original image, it will be the approximation of the original image. Figure 1 below shows a fundamental model of image degradation and restoration procedure.

III. FUNDAMENTALS OF IMAGE RESTORATION

Image restoration is a restoring or recovering process of a degraded image by utilizing some prior knowledge of degradation method which has degraded the image. So the image restoration process involves the estimation of the deteriorated model as well as the relevance of the inverse filtering to restore or retrieve the original image [24]. Although the reconstructed image may not be the exact form of the original image, it will be the approximation of the original image. Figure 1 below shows a fundamental model of image degradation and restoration procedure.

In spatial domain, the degradation of the original image can be modeled as [25]:
\[ g(x, y) = h(x, y) * f(x, y) + n(x, y) \]  
(1)

Where, 
\[ (x, y) \] = detached pixel coordinates of the image frame.
\[ f(x, y) \] = Original image
\[ g(x, y) \] = Degraded image
\[ h(x, y) \] = Image degradation function
\[ n(x, y) \] = Add-on noise

As convolution operation within the spatial domain corresponds to multiplication in the frequency domain, the equation 1 can be rewritten as:
\[ G(u, v) = H(u, v) \times F(u, v) + N(u, v) \]  
(2)

Now, Motion blur is present when there exists comparative motion in the midst of the recording device and the scene (object). However, the types of blur may be in the appearance of a translation, rotation, and scaling, or some combinations of these. Here only the critical case of a global translation will be considered.

Let’s pretend the scene to be recorded interprets comparative to the camera at constant velocities a and b along the directions of x and y during the exposure time T. The frequency domain degradation function can be simplified as [26]:
\[ H(u, v) = \frac{\sin(\pi(ua + vb)T)}{\pi(ua + vb)} e^{-j\pi(ua + vb)T} \]  
(3)

Image restoration process can be subdivided into two classes:

- Deterministic methods are applicable to images with a small amount of noise and a familiar degradation function.
- Stochastic techniques are to restore images according to some stochastic criterion.
A. The Basics of Inverse Filtering

Like any other unsupervised methods such as Fuzzy C-Means [27] and ADBSCAN [28] clustering, inverse filtering is also unsupervised. The basic image restoration model for inverse filtering is exposed in figure 2.

When the degradation function \( H(u,v) \) is identified, the image can be returned to normal state by:

\[
\hat{F}(u,v) = \frac{G(u,v)}{H(u,v)} \quad \text{(4)}
\]

Now, in our case, we have added noise after implementing the motion blurring effect. Hence we have used the following formula to restore the original image:

\[
\hat{F}(u,v) = F(u,v) + \frac{N(u,v)}{H(u,v)} \quad \text{(5)}
\]

Since, the function of \( N(u,v) \) is random whose Fourier transform is generally unfamiliar, it is impossible to retrieve \( F(u,v) \) accurately. The impact of noise is noteworthy for frequencies where \( H(u,v) \) has a tiny magnitude. In reality, \( H(u,v) \) usually decreases in size much more rapidly than \( N(u,v) \) and thus the noise effect \( N(u,v)/H(u,v) \) could take over the entire restoration result.

B. The Basics of Wiener Filtering

The basic image restoration model for Wiener filtering is modeled in figure 3.

Wiener filter exploits the previous knowledge of the spectral properties of the original signal and the noise and linear time-invariant rule to produce an output as close to the original image as feasible. In wiener filtering, it is presumed that the signal and noise are static linear stochastic processes with familiar spectral properties [29, 30]. Wiener filter tries to reconstruct the degraded image by minimizing an error function as designed by the following equation:

\[
MSE = E[\{f(x,y) - \hat{f}(x,y)\}^2] \quad \text{(6)}
\]

Where,
- \( MSE \) = Mean square error
- \( E[\cdot] \) = The expectation operation
- \( \hat{f}(x,y) \) = Restored image

The Wiener filter is to locate an approximation \( \hat{f}(x,y) \) of the original image \( f(x,y) \) so as to the mean square error between them is minimized. Wiener filter is represented as \( L(u,v) \) as shown below [31, 32]:

\[
L(u,v) = \frac{H^*(u,v)S_f(u,v)}{|H(u,v)|^2 S_f(u,v) + S_n(u,v)} = \frac{H^*(u,v)}{|H(u,v)|^2 + S_n(u,v)} \quad \text{(7)}
\]

Again,

\[
L(u,v) = \frac{H^*(u,v)S_f(u,v)}{|H(u,v)|^2 S_f(u,v) + S_n(u,v)} = \frac{1}{|H(u,v)|^2 + K} \quad \text{(8)}
\]

Where,
- \( K = \frac{S_n(u,v)}{S_f(u,v)} \)
- \( S_f(u,v) = \) Power spectrum of the original image
- \( S_n(u,v) = \) Noise power spectrum

Here, \( K \) is the inverse of SNR. The image and noise are considered as arbitrary processes. The Wiener filter can generate optimal estimate only if such stochastic processes are stationary Gaussian. These situations are not typically satisfied for real images. So the restored image can be expressed as:

\[
\hat{f}(u,v) = L(u,v)G(u,v) \quad \text{(9)}
\]
IV. RESULTS AND DISCUSSION

For this paper, the following color image of a car is used as made known in figure 4.

![Car Image](image1.png)

Fig. 4. The color image of a car

Then the image is transformed into a grayscale image in Matlab. The grayscale image is made known in figure 5 below.

![Grayscale Image](image2.png)

Fig. 5. The grayscale image of figure 1

Now, the first task was to insert motion blur effect into the image according to equation (1). After doing so, the resulted image is represented in figure 6.

![Motion Blurred Image](image3.png)

Fig. 6. Grayscale car image with motion blur effect

The effect of the motion blur can be controlled by a and b components of the model.

After applying the blur to the image inverse and, Wiener filterings are implemented to restore the image.

A. The Results of Inverse Filtering

For inverse filtering, if we do not add any noise after the motion blur, then we can restore the same image before motion blur. The figure 7 below shows the effectiveness of inverse filtering without any noise.

Now, if we add some random noise to the image, then the filter performance degrades to some extent. The consequence of noise on the performance of inverse filtering is made known in figure 8. In figure 8, though the inverse filter is capable of inverting the effect of motion blur, it is not able to nullify the effect of noise. Here, a=0.0001 and b=0.1.

![Inverse Filtering Results](image4.png)

Fig. 7. Restoration of motion blurred car image by inverse filtering
B. The Results of Wiener Filtering

The Wiener filter has a ‘K’ component which is inverse to the SNR. Now, if the noise power is zero, which means no noise, then the Wiener can restore the exact image which was corrupted by motion blur effect. In the following case, we have considered zero noise power, and figure 9 shows the performance of the Wiener filter. Here, the restored image is almost exactly similar to the image before motion blur. However, if we change the k to 0.01, then there would be 1% noise added after the motion blur effect. If then we apply wiener filter, we will get the following result as represented in figure 10. It is observed that the Wiener filter is reversing the effect of motion blur, but still, there is some noise remaining in the picture.
V. CONCLUSION

This paper presents inverse and Wiener filterings’ practical implementation on some images for image restoration. It is observed that both inverse and Wiener filtering work quite well in the absence of noise in restoring original image from its degraded version. But in the existence of additive noise Wiener filter works better for restoration purpose compared to inverse filtering. In subsequent works of this series, some other improved filtering techniques for image restoration will be discussed.
