15 **Abstract:** This paper presents the results of a recent study that was conducted with a number of
 16 German municipalities/cities. Based on the obtained and briefly presented recommendations
 17 emerging from the study, the authors propose the concept of an Urban Data Space (UDS), which
 18 facilitates an eco-system for data exchange and added value creation thereby utilizing the various
 19 types of data within a smart city/municipality. Looking at an Urban Data Space from within a
 20 German context and considering the current situation and developments in German municipalities,
 21 this paper proposes a reasonable classification of urban data that allows to relate the various data
 22 types to legal aspects and to conduct solid considerations regarding technical implementation
 23 designs and decisions. Furthermore, the Urban Data Space is described/analyzed in detail, and
 24 relevant stakeholders are identified, as well as corresponding technical artifacts are introduced.
 25 The authors propose to setup Urban Data Spaces based on emerging standards from the area of ICT
 26 reference architectures for Smart Cities, such as DIN SPEC 91357 "Open Urban Platform" and EIP
 27 SCC. Thereby, the paper walks the reader through the construction of an UDS based on the above
 28 mentioned architectures and outlines all the goals, recommendations and potentials, which an
 29 Urban Data Space can reveal to a municipality/city.

30 **Keywords:** data governance; data sovereignty; urban data spaces; ICT reference architecture; Open
 31 Urban Platform

32

33 **1. Introduction**

34 The "data-driven transformation" influences the economy and society in an increasing manner.
 35 This development constitutes the so-called "transformation phase" towards a global "data economy".
 36 In parallel, a continuously growing amount of data is being generated thereby building on new
 37 technological trends such as the Internet of Things, factories of the future, artificial neural networks,
 38 big data analytics, autonomous networked systems or Smart City reference architectures. Digital
 39 data and information provide the basis for these new technologies.

40 The "data economy" in that sense comprises an ecosystem of different stakeholders and market
 41 participants, such as companies, infrastructure managers, public administration, research and civil
 42 society, whose cooperation ensures that data can be made accessible and usable. In this context, the
 43 market participants/stakeholders can extract and derive value from this data by implementing and
 44 operating a variety of ICT applications/services opening a tremendous potential for improving our

45 everyday lives, including vital aspects such as traffic management, traffic flow optimization or
46 remote e-health services [1].

47 According to the European Commission [1], public and private (service) providers can benefit
48 enormously from the emerging new data market. Municipalities are also part of this ecosystem and
49 also have the potential to contribute and benefit. For municipalities, the first steps would be to
50 examine, understand and define their own specific urban data, to work out and implement the
51 necessary processes for data provisioning and data management, to build a powerful data
52 infrastructure to support and automate these processes, and to ensure their own municipal data
53 sovereignty.

54 The enormous variety of data in the municipalities offers plenty of options/potentials in many
55 different perspectives: for example, information and insights for integrated urban development,
56 urban environmental protection and policy-making can be gained and the local economy
57 strengthened, for instance with new business models and innovative data-based ideas. Often
58 however, systematically executed overviews are lacking details about the data available in
59 municipal organizations. The usage of these data is mostly restricted to limited areas in local
60 governments. This reinforces the partially existing silo thinking within different domains and
61 between individual departments. In addition, German and European municipalities often lack the
62 technical infrastructure that enables a horizontal connection between the various municipal actors
63 and supports the integrated use of data, as well as concrete municipal business models for
64 sustainable data exploitation. Furthermore, the municipal data economy is also hampered by the fact
65 that a regulation regarding the utilization of created, transmitted and utilized data is missing [2],
66 and hence the question of communal data sovereignty is not sufficiently and practically answered as
67 to enable the utilization of large amounts of municipal urban data. German and European
68 communities/municipalities should now take action and secure their participation in the data
69 economy. On the way to a modern, sustainable and networked city or community, communities
70 must be accompanied and supported.

71 The basis for the creation of the Urban Data Space, which can be understood as a "precursor" for
72 "smart cities / communities", is a clear overview of the existing urban data as well as an easy retrieval
73 of and integrated access to the existing urban data. The Urban Data Space should offer a
74 comprehensive range of municipal data as well as an overarching usability of the data in the overall
75 communal context. In order to review the current situation of German municipalities, the present
76 study provides an inventory analysis of municipal data and legal framework conditions in selected
77 German municipalities. The following questions are of central importance: 1) What characterizes the
78 urban data? 2) Which data is already available in the municipal databases of the examined model
79 regions? 3) Which urban actors are interested in data exchange? 4) How are the legal framework
80 conditions? 5) How can an IT/ICT architecture be designed sustainably for urban areas? Based on
81 these questions and taking into account the German "Smart City Charter" [3] and the "Sustainable
82 Development Goals of the 2030 Agenda" [4], the present study formulates recommendations that
83 should orientate municipalities on how to efficiently design a future-proof Urban Data Space.

84 The rest of this paper is organized as follows: Section 2 analyzes the frame (including data
85 classification) for Urban Data Spaces and defines the proposed concept. Section 3 presents briefly the
86 results from the study relating to UDS and conducted in multiple German cities and municipalities.
87 Section 4 proposes an abstract design for an Urban Data Spaces and analyzes the benefits for
88 cities/municipalities thereby clearly outlining the required steps towards a successful large-scale
89 implementation. The following section 5 shows how the important aspects of data governance and
90 data sovereignty would be addressed, whilst the final section 6 concludes this paper and presents
91 potential future research and development directions.

92 2. Analyzing the Frame for an Urban Data Space

93 In addition to the data-owner-related classification presented below, there are various data
94 collection/gathering/acquisition options that are currently used in the urban environment. The
95 variety of methods used is very wide and includes statistical procedures, as well as data collection

96 methods within the public administration (for example, by reporting obligations), but also
97 sensor-based approaches in the context of the Internet of Things, which are increasingly used in the
98 course of the digital urban transformation. Selected relevant examples of data collection methods in
99 the Urban Data Space are presented in appendix A.5 in [5]. The examples are chosen to reflect the
100 latest state of research in EU projects and national projects. It should be emphasized that besides
101 these examples, of course, there are also the traditional methods that are currently practiced in
102 municipalities. Good examples here are the established statistical offices and geo-data offices, whose
103 proven data collection methods provide a rich source of data for the Urban Data Space. After this
104 brief discussion on possible data collection/gathering methods, the presentation on providing data
105 for the Urban Data Space continues with further details in the coming section.

106 2.1 Data Classification

107 The term "**urban data**" refers to all types of data that are important in the urban context,
108 regardless of the specific data origin, data management, the associated intellectual property rights
109 and licensing requirements. Urban data may include data that extends beyond the direct local
110 context, for example, when needed for a municipal process based on data of supra-regional or
111 global relevance, or simply if it has general effects on the urban space/environment - for example,
112 climate data or financial data.

113 The Urban Data Space refers to the entire set of data that has relevance in the urban context
114 (economic, urban, geographical, technical, climatic, health, etc.) and is needed, generated or
115 collected within municipal processes. The "smart city / community" concept intends to open up this
116 data such that the municipality or the municipal companies can facilitate and accelerate the
117 corresponding provisioning processes. The ICT-based services and applications of the municipality
118 should also utilize this data. Data can be provided directly as a good or used as a basis for
119 innovative services.

120 The proposed concept within "Data for London: A City Data Strategy" [6] treats the term "city
121 data" as a central element of an embodiment of the Greater London as intelligent, urban, ICT-based
122 ecosystem. Great emphasis is placed on the successful implementation of relevant open-data
123 strategies¹. The so-called "Data for London Strategy" plans to extend these approaches by additional
124 types of data and corresponding data providers. This complementary data is expected to come not
125 only from the public administration, but also from the private sector. Data providers can be urban
126 utilities, as well as various infrastructure operators, distributors, start-ups and many more.

127 2.1.1 Official Institutional Data

128 Official data refers to all data available from/for public-law institutions performing
129 administrative tasks. Examples of such data are from official statistics, i.e. statistics compiled by an
130 official institution, in particular a statistical office or (for example) official surveying of conducted by
131 the responsible institutions. Further examples for official data in urban environments are also given
132 by data from public offices, cadastres or municipal utility data, such as water supply data and
133 energy data, if organized under public law.

134 2.1.2 Enterprise Data

135 As enterprise data, we refer to all data arising within a company. Enterprise data can be
136 obtained within a company itself or from external sources, such as market and customer data,
137 consumer behaviour or business relationships. For example, the data from the purchase of raw

¹ For example data.gov.uk and data.london.gov.uk.

138 materials, consumables and supplies can be commercially available for production plants and with
139 respect to final products. Even companies can provide data as open data, as exemplified by the Open
140 Data Portal of the Berlin energy provider (see: netzdaten-berlin.de).

141 A major obstacle for the exchange of enterprise data is given by the risk that the provided data
142 might contain corporate secrets. Relevant data (in the domain of data-driven companies) could
143 potentially include source code, algorithms or entire repositories, theoretical models, system
144 architectures or other modelling artifacts, e.g. UML diagrams, use cases and other functional
145 descriptions. As long as industrial property rights do not address data aspects and technical
146 infrastructure, it is up to the company to determine to what extent certain internal enterprise data
147 artifacts should remain protected [7].

148 2.1.3 Research Data

149 According to a definition of the alliance of German science organizations, research data is data
150 *"that arises in the course of scientific projects, for example based on digitalization, desktop research,*
151 *experiments, measurements, surveys or questionnaires"* [8]. Research data can include measurement data,
152 laboratory results, audiovisual information, data from studies, samples and probes that originate
153 from, are developed or evaluated in the course of scientific work, as well as methodological test
154 procedures, such as questionnaires, software or simulations [9]. In the scope of providing research
155 data into a research data space, various German science organizations and the "Council for
156 Information Infrastructures" (RfII) are currently working on setting up a German-wide "National
157 Research Data Infrastructure" (NFDI).

158 2.1.4 Personal Data

159 Personal data relates directly to physical persons, or allows concluding on different aspects
160 relating to physical persons. In addition to general personal data such as address and age, further
161 examples are given by bank details, hair colour or dress size. Personal data is subject to the General
162 Data Protection Regulation (GDPR) and may potentially be generated in companies, offices or even
163 in research.

164 In case of a personal reference within a dataset, the further usage is generally limited due to
165 privacy protection issues. The data protection regulations legitimize extensive processing only with
166 the existence of a legitimate legal basis and compliance with the data protection principles required
167 by the GDPR. Special care should be taken of so-called "special personal data" referring to
168 particularly sensitive data such as information on ethnic and cultural origin, political, religious and
169 philosophical beliefs, health, sexual orientation and further.

170 In the case of personal data, physical persons are entitled to "informational self-determination".
171 For companies, authorities or third parties in general, the storage and processing of personal data is
172 therefore only permitted with the consent of the data subject, i.e. the person the data refers to. In
173 addition, physical persons have the right to inspect the data stored about them within
174 companies/authorities and to initiate its deletion if necessary. Companies and authorities that want
175 to process personal data or even use it commercially must pay special attention to belonging data
176 protection issues and regulations.

177 2.1.5 Behavioural Data

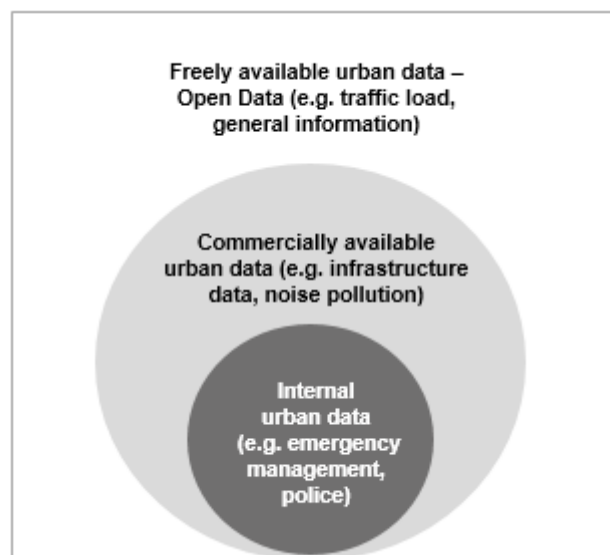

178 Behaviour data is given by digital data of/from citizens, which emerges based on their
179 behavioural patterns. Such digital information is based on automatically generated/obtained
180 samples based on the behaviour of citizens involved with some sort of sensor equipment (e.g.
181 heartbeat sensors, GPS, smartphone-based sensors ...). Data obtained in a machine-generated or

182 automated manner remains property of the corresponding citizens, no matter if it is anonymized or
 183 personalized, or if the data has been further processed and new information has been produced
 184 through interconnections and data center computations.

185 Recent German data eco-system studies [10] handle the "behavior-generated personal data"
 186 from the perspective of individual property. Behaviourally generated personal data must therefore
 187 be clearly distinguished from the data protection law term "personal data". In other words: the main
 188 subject of data protection legislation is personal data, whilst the subject of data ownership legislation
 189 should be correspondingly given (in this context) by the behaviour-generated data. Existing legal
 190 loopholes on the subject of "data ownership" call for the introduction of a primary intellectual
 191 property right/law for behaviour-generated information of citizens. German consumer
 192 organizations are therefore calling for a clear classification of data, in order to determine the scope of
 193 ownership, and correspondingly the scope of the exploitation rights [10].

194 2.1.6 Freely Available Data

195 The term and the need for "freely available data" is closely related to the "open data" and "open
 196 government" movement (as illustrated in Figure 1), which build on "freely available data" as follows:
 197 a) in general, significant impulses for the improvement of political, social and economic data
 198 promoting social cooperation are expected (keywords: participation, transparency and cooperation)
 199 [11]. The open data/government movement continues to assume that freely available data b)
 200 contribute to better forms of governance (i.e. better governance in general) and c) provide various
 201 added values for policy, administration and citizens at the procedural level, for example by
 202 promoting "open innovation". Freely available databases have great innovative potential for
 203 business, administration and society, as well as for social innovation and economic development
 204 [11].

205

206

Figure 1: Data Layers in an Urban Data Space.

207 It should be noted again that the term "freely available data" is not synonymous with the term
 208 "open data". "Open data" is when public data is freely available to the public without restrictions.
 209 Data provisioning and usage subject to restrictive licensing terms - that is, usage restrictions
 210 opposing established open data licenses - contradict the understanding of open data [12]. In such
 211 cases, we have to deal with "closed data" or "shared data".

212 As part of the Smart City activities of recent years, "open data" has been given high priority.
 213 Various "Smart City / Community" initiatives [13][14][15][16] have been advocating for urban

214 development in the direction of urban digitalization and ICT-based ecosystems for urban
215 environments - both in Germany and in the broader European context. This is expected to be
216 realized with the help of administrative data and its provision or "opening" via corresponding open
217 data portals. Examples are the open data portals of Berlin (daten.berlin.de), Cologne (open data -
218 koeln.de), the transparency portal Hamburg (transparenz.hamburg.de/open-data/) and GovData.DE
219 as the data portal for Germany, which was initiated by the Federal Ministry of the Interior. Since
220 such data are usually already available in the municipalities, many of the "smart city / community"
221 pilot projects carried out throughout Europe in recent years have called for the completely free
222 opening of public databases. Many ICT research projects initially had to limit themselves to open
223 data as a data base or to generate data by crowd-sourcing for the concrete project needs, since other
224 data was not available for technical, licensing or business reasons. For example, EU projects in the
225 area of Sustainable Mobility showed interest in the mobility data coming from navigation system
226 manufacturers [17]. This data could not be used in the project in general because it was not freely
227 available for research projects.

228 The open data concept continues to play an important role in the context of the establishing
229 urban ecosystems and platforms as well as in all major international and national strategies,
230 roadmaps, collaborations and standardization relating to this topic. Further basic definitions of open
231 data are given by the preliminary study on the GovData.DE portal and by the Sunlight Foundation
232 [18]. The open data activities in Germany are promoted by studies such as the current report [19] of
233 the "Technology Foundation Berlin" on the status quo of open data in the Berlin administration.
234 Among other things, this study notes that there is often a lack of clear responsibilities for the subject
235 of data publication and provisioning. In this sense, it is recommended to set up a special body to
236 coordinate the data publishing/provisioning activities of the municipality. This body would need to
237 have the necessary authority to view the databases and prepare them for reuse within the individual
238 offices and units -such processes are of high importance for systematic data publishing and
239 provisioning.

240 2.1.7 Commercially Available Data

241 Commercially available data - as pictured in Figure 1 - can be generated by either private or
242 public agencies/institutions. Typically, this type of data is provided by companies that are interested
243 in selling the data. Accordingly, the "London Data Strategy" [6] defines "commercial data" as being
244 distributed under a license that allows re-use and processing strictly only in exchange for a
245 monetary payment. Companies that sell commercial data are, for example, map or navigation
246 system manufacturers, energy companies, mobile service providers or even post companies. For
247 example, mobile communication providers can sell analysis data of traffic and mobility streams
248 based on anonymous wireless network signalling data. This data enables so-called "geo-marketing
249 insights", i.e. insights into urban matters that previously could not be analyzed, or could be
250 understood only with great effort. These findings can be of significant interest to different actors
251 (industry, service providers, political parties etc.). For instance, such data can provide information
252 about the number of road users traveling between two districts or cities. Based on such information,
253 the volume of traffic on a route in the ecological and social sense can be influenced. In particular,
254 similar evaluations can significantly support strategic decisions and operational improvements in
255 transport and other sectors.

256 In general, companies do not distribute **primary data** (for example, customers' activities within
257 the mobile network). Normally, commercially available data is published as secondary data.
258 **Secondary data** is generated after further processing steps from primary data. Possible processing
259 methods of primary data can be: aggregation, generalization, interpretation and classification. For
260 example, (primary) data is often tailored to specific customer needs and anonymized and filtered
261 based on data protection legislation, so that no conclusions are drawn to individual persons and
262 thus the privacy of the citizens can remain protected. Data driven enterprises or authorities spend

263 considerable resources (for example, for data analysts) and infrastructure (such as high computer
264 capacities), which have to be financially reflected in the final price for data.

265 Currently, the question remains as to how so-called behavior-generated data, which is often
266 commercial data, can ideally be provided as part of an Urban Data Space. So far, the problem in the
267 area of corporate data is solved – e.g. in the context of traffic planning such data is handled based on
268 jointly concluded contracts between data companies and the city/municipality. Currently, the
269 question of data ownership for behavior-generated data of citizens is discussed in a German debate
270 on the introduction of a new "data ownership" legislation [10].

271 2.1.8 Internally Available Data and "Publicly unavailable Data"

272 Internal data are generally those data which are available within the authorities, companies or
273 reside in private ownership, and which for various reasons cannot or should not be made available
274 to the public as raw data – see Figure 1 for the position of such data within the data layers of an
275 urban environment. Mostly it is data that is intended for internal organizational purposes. Hence,
276 publication and external use is not considered.

277 In principle, institutional (public) administration data in Germany should be openly available.
278 This is the situation according to the belonging law governing access to information of the Federal
279 Government (Freedom of Information Act – IFG)². It also applies to other federal bodies and
280 institutions as long as they carry out public-law administrative tasks. The belonging authority can
281 and should (upon request) provide information, grant access to a requested file or provide
282 information in any other way.

283 2.2 Data Access and Data Sovereignty

284 The current legal situation (related to the legal rights of data use) is still unsatisfactory. For
285 different types of data, different usage rights apply depending on the context and varying between
286 the domains. For years, a national and international political discourse has been ongoing about these
287 imperfections of data laws and the potential creation of new legal frameworks for data ownership
288 [25]. As indicated, it is still a matter of debate whether data can even be conceived as individual
289 private property, i.e. whether data can be treated more or less like material or intellectual property.
290 Furthermore, within the previous paragraphs we outlined the pending loopholes regarding the
291 classification of behaviourally generated data and its ownership assignment. Further issues are
292 related to data exclusivity rights, or to whether clarifying rights to data utilization over contracts is
293 sufficient. It is also unclear in most cases how data access rights can be defined and how this affects
294 the business models and the evolution of a data economy. As part of building the data economy, the
295 complex "data ownership, data sovereignty, data exploitation and data protection" aspects reveal
296 numerous clarification needs.

297 There have been various interpretations of the term "data sovereignty" in use by political parties
298 in Germany. Basically, the debate about this term is about the right to assign data to a person that is
299 not already covered by existing regulations. If one explains the term in the light of the various
300 arguments in the social and political discussion, two interpretations best cover the general
301 understanding of "data sovereignty": a) sovereignty in terms of data protection and b) sovereignty in
302 the sense of a property-like view.

² In German: „Gesetz zur Regelung des Zugangs zu Informationen des Bundes (Informationsfreiheitsgesetz – IFG)“

303 2.3 The Urban Data Space

304 The emergence of the term "data space" is recent and related to the emergence of the concept of
305 the "European data economy".

306 In April 2018, the Commission presented the follow-up strategy paper on the European Data
307 Economy - "Building a European Data Economy" [22]. It places the notion of a data space in the
308 context of a data economy and emphasizes the fact that the digital transformation is not limited to a
309 social scope (such as for example focussing on economic aspects), but that it encompasses all areas
310 of life. In its communication note, the EU defines the "**European Data Space**" as "*a seamless digital
311 territory on a scale that enables the development of new data-based products and services*" [23].

312 Data spaces contain data and serve as enablers of digital services - as for example linked data
313 semantic and web technology based platforms and services [24]. The term Data Space is applicable
314 only to digital data. Digital data refers to basic data (raw data), value-added data (processed data),
315 meta-data (data describing basic data and value-added data) and derived information (often
316 derived from data by means of combining various data sets towards logically obtaining facts or
317 interpretations) - all called data for short. The Data Space applies to this data, but also to technical
318 data stores and various types of data processing. The Data Space can also have a spatial scope. For
319 example, the term "European Data Space" clearly refers to the territory of the European Union.

320 In institutional and personal terms, one can imagine a Data Space as a network of actors. From
321 a technical point of view, the Data Space is a data infrastructure with technical standards, where
322 data can be securely exchanged and linked between actors in the Data Space. In legal terms, the
323 Data Space can be constructed as a separate entity with rules in a clear legal framework that should
324 be entitled to "data security" as well as "data sovereignty"[9] of its participants. Functionally
325 speaking, the Data Space can be understood as a demand-oriented system that can be actively
326 shaped by its actors [25].

327 Within the emerging data economy, various decentralized "Data Spaces" can be identified. In
328 particular, Data Spaces differ in terms of spatial, legal and economic objectives. Data Spaces can be
329 identified at European, national, regional or local level, separated from each other in terms of their
330 actors (e.g. industry, municipalities) or domain-specific (e.g. mobility data space, energy data space,
331 medical data space, research data space etc.).

332 As an "**Urban Data Space**" we refer to such a Data Space containing all kinds of data that may
333 be relevant to the urban community as well as to the urban economic and policy space. Ideally,
334 based on the "smart city / community" concept, it encompasses all data relevant to the municipalities
335 and their stakeholders from all domains (energy, mobility, health etc.) in urban environments that
336 arise in both analog and digital environments.

337 The boundaries of an Urban Data Space are not necessarily within a specific municipal space.
338 An Urban Data Space can also be extended to the dimensions of an economic area that is important
339 for the municipality, as well as to the associated administration, living, but also legal, experience,
340 action, identification, communication and socialization space. The Urban Data Space includes all
341 data generated by persons, companies and/or machines (personal and non-personal) as well as
342 behavioral data (i.e. data generated by human behavior), be it internal, commercial or freely
343 available, provided that it is closely related to the corresponding urban space.

344 The objectives of an Urban Data Space are: 1) the increased availability and utilization of urban
345 data, 2) improved access to and better transmission of data within the municipal administration,
346 municipal enterprises and other stakeholders, 3) the transparency when handling non-personal
347 data, 4) technically sound concepts for data security/protection and improved data quality, 5)
348 interoperability and standardization of urban databases and communication protocols, 6) the
349 development of municipal and regional data analysis; 7) the promotion of data-based business
350 models in urban areas by the state and municipalities and in promoting development opportunities
351 for innovative business ideas of small and medium-sized enterprises in the municipal area, 8)
352 building a flexible technical IT infrastructure that integrates all available meta-data and data, and 9)
353 the liability and security related to the utilization of innovative technology.

354 2.4 Stakeholders in the Urban Data Space

355 When building up the data infrastructure for an Urban Data Space, the diverse interests of all
356 stakeholders should be taken into account and their potential involvement and contribution to the
357 overall eco-system supported. The "smart city / community" concept calls for the actors to provide
358 the most interesting possible data (real-time data, big data ...) within the Urban Data Space so that
359 diverse and innovative utilization scenarios are facilitated. The "network of actors" of the Urban
360 Data Space can be structured as follows [6]: 1) **Structural actors**: Urban Data Space operators (UDS
361 operators) are the actors who actively shape the digitalization strategy, operate and promote the
362 data infrastructure and data usage in urban areas (e.g. mayor, public services, private sector
363 representatives, universities, regulators, standardization bodies, ethics council ...), 2) **Supporting**
364 **actors**: data providers (UDS data providers), providers of IT services as well as public and
365 commercial data providers; organizations involved in the provisioning and operation of the urban
366 infrastructure and handling the data (e.g. municipal companies, telecommunication companies,
367 private sector, transport networks ...), 3) **Contributing actors** as users of the Urban Data Space (UDS
368 users) and the belonging data infrastructure. These could be stakeholders such as developers of
369 data-driven business models or citizens (e.g. data enriching collaborators, integrators, consumers
370 and others). **UDS data providers** publish data in conjunction terms of use and charges, or free of
371 charge depending on the underlying operational and business model. The following (data)
372 providers can play a significant role within an Urban Data Space (either based on terms of use and
373 charges, or free of charge): 1) municipalities and municipal companies, associations, 2) commercial
374 enterprises, 3) research, 4) citizens, 5) offices and organizations of the public sector, 6)
375 non-governmental organizations (NGOs) etc. UDS operators ensure the secure and trustworthy
376 operation of the Urban Data Space. UDS users must respect the terms of use and, if necessary, pay
377 fees. For the classification of the urban data, it can be further said that its terms of use may permit
378 only a purely (provider) internal use. That is, use is restricted to a group of providers or users. On
379 the contrary, a public usage can be allowed that is free or requires a monetary value in return.

380 2.5 Smart City and Communities ICT Reference Architecture

381 In order to optimally structure and sustainably use all urban data in the sense of a smart city,
382 the technical structure of a data platform is required - a data platform can link together all the
383 available urban data. A data platform that extends horizontally across all domains of a municipality
384 and that can access all the required data is seen as a fundamental part of a Smart City / Community
385 ICT infrastructure. An appropriate data platform as a database is included in all ICT reference
386 architecture models for smart cities.

387 In the past few years there was increased research effort relating to the concept of an ICT
388 reference architecture for "smart cities and communities". Various ICT reference architectures have
389 been developed and tested in a number of European and national research projects. Reference
390 architectures and models are increasingly used in telecommunications and the Internet domain,
391 thereby enabling global networking and communication of data, video and voice. Two of the most
392 prominent reference models are given by ISO/OSI [26] and TCP/IP [27], which have unified
393 telecommunication and Internet communication architectures and provide a common
394 understanding for sustainable development of global communication technology. The development
395 of these two protocol families has facilitated the Internet and the digitalization of our societies in the
396 first place. In particular, ISO/OSI and TCP/IP protocols provide inter-device interoperability - e.g.
397 ranging from switches, routers, media gateways, to end user terminals such as smartphones, tablets,
398 and desktops - from various manufacturers.

399 Another reference framework that has gained relevance in recent years is TOGAF (The Open
400 Group Architecture Framework) [28], which is increasingly being used in the development of
401 enterprise architectures. TOGAF has inspired some of the key activities/collaborations on urban ICT
402 reference architectures in recent years - for example, DIN SPEC OUP 91357 [16] and EIP SCC [15].

403 With respect to reference architectures for ICT in smart cities, the Smart City Charter of the
404 German Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR)
405 [3] explicitly states that the development of an open reference architecture in the urban context will
406 lead to a structured and flexible way of digitalizing a municipality. A reference architecture will
407 promote the integrative cooperation of several vendors and support the sustainable
408 extension/enhancement of the ICT infrastructure through new software and hardware modules.

409 The European Initiative "The Marketplace of the European Innovation Partnership on Smart
410 Cities and Communities" (EIP SCC) [14] summarizes the concept of a reference architecture as a tool
411 to support the smart cities and communities, an abstract IT-technical perspective for the realization
412 of an urban ICT infrastructure. On the other hand, the abstract approach of the reference architecture
413 as a blueprint allows for the consideration of specific needs of the community by strengthening the
414 resulting real technical architecture of the community/municipality/city - as a result of the reference
415 architecture through standards, open interfaces and interoperability aspects. Moreover, it is a basic
416 assumption that an ICT reference architecture integrates or connects existing ICT solutions in the
417 Urban Data Spaces. Existing systems should remain in place, but at the same time fit into the new
418 structure. This requires improving their interoperability or the interoperability of the entire existing
419 technical architecture within the municipalities. The main goal of a generic reference architecture is
420 to enhance these real technical urban IT architectures and enable their sustainable extensibility and
421 scalability, while at the same time reducing dependence on individual vendor/operators (vendor
422 lock-in effects). Finally, a reference architecture provides a common terminology that applies to all
423 urban spaces and enables technical discussions between different actors.

424 According to our understanding, we define an ICT reference architecture as follows: An urban
425 ICT reference architecture sets itself the goal (1) of describing an abstract structure of the ICT
426 infrastructure and related interactions, especially between the utilized ICT components. Based on
427 this abstract structure, (2) an ICT reference architecture creates an ecosystem for information and
428 communication technology in the urban context, in which various actors can participate. This
429 ecosystem is (3) open to SMEs, large corporations, open source initiatives and related open source
430 software modules. By applying a reference model, the (4) classification and interaction of different
431 ICT components is supported via open, standardized interfaces/APIs within the reference
432 architecture, such that the (5) implementation of "smart city / community" scenarios based on
433 integrative solutions is ultimately enabled. In addition, the continuous (6) extension of the municipal
434 ICT infrastructure is ensured by the addition of further components according to the rules of the
435 applied reference architecture. In particular, by using a reference architecture, it is possible to (7)
436 replicate ICT-based smart city/community solutions between municipalities, and (8) further exploit
437 the combination of components from existing Smart City solutions and adopt in an integrative
438 pattern into new innovative urban services and applications. It is particularly important to note that
439 an ICT reference architecture does not pursue a disruptive approach, but an evolutionary one that
440 (9) takes into account the existing ICT systems and maps/positions them within the framework of the
441 reference model.

442 3. Analysis of the Situation in selected German Cities

443 When choosing the model municipalities, various aspects were considered of particular
444 importance: Interested municipalities should have an advanced status with regard to the systematic
445 management of urban data and the existence of established IT departments. It was also important
446 that the municipalities actively shape the interaction between administration, urban society, science
447 and digitalization activities, and express an interest in actively supporting the study. Furthermore,
448 recommendations from the German Organization of Municipal Enterprises (VKU – Verband
449 kommunaler Unternehmen) on interested municipalities were taken into account.

450 As a basis for carrying out the analysis, an inquiry form was first designed to query various
451 aspects of the Urban Data Space. It serves to record the IT systems that municipalities and municipal
452 companies work with. Based on this, the data - with which the systems work - was analysed in
453 further detail. In addition, the questionnaire includes sets of questions on strategic aspects of the

454 Urban Data Space, such as collaboration, strategic frameworks (concepts and documents), and the
455 potential use cases for the available data. The legal part of the questionnaire includes legal
456 framework conditions, as well as licenses and data usage rights/rules in place within the involved
457 municipalities. The questionnaire can be found in [5].

458 The contact persons in the municipalities received the questionnaires with the request to
459 complete them independently, as far as possible. Based on this, (semi-) structured interviews were
460 conducted with various employees from local government and municipal companies. The selection
461 of the persons to be interviewed was carried out by the municipalities.

462 Based on the results from the conducted interviews and performed analyses, different
463 hypotheses are drafted which contain generalized statements for the data situation in the German
464 municipalities. These statements serve as the basis for recommendations considering the strategic
465 framework, the data diversity, the cooperation, the IT infrastructure, the interoperability and
466 economic aspects of data utilization towards establishing viable Urban Data Spaces. The following
467 paragraphs contain only a high-level summary of the situation in the selected German cities as well
468 as the recommendations on German national level for the cities/municipalities to consider towards
469 the implementation of their Urban Data Spaces. The detailed results of the conducted studies can be
470 found in [5].

471 3.1 Emden

472 The situation analysis in Emden shows that the city is pursuing a structured methodological
473 approach to digitalization. In particular, based on an established digitalization roadmap, an
474 important tool is put in place, which represents a "manual" for execution of the local Smart City
475 project.

476 The selected approach regarding the identification of suitable business models is an interesting
477 way to kick-start the activities towards establishing an urban data platform and correspondingly an
478 Urban Data Space. Whilst normally new technologies (e.g. data platforms) are directly introduced in
479 German and European cities, it is first checked and analysed in Emden whether the introduction of
480 an IoT platform can be supported by sufficiently viable business models. Since not yet existing in
481 Emden, the introduction of commercial and crowd-sourced data could provide corresponding
482 potential within the design of urban data and belonging platforms, and ultimately in the
483 identification of other business models. The previously selective exchange of Emden with the
484 municipality of Monheim or other municipalities, which already use commercial data, could be
485 extended into a strategic cooperation, so that in the long term the experiences can be re-used and
486 new ideas can be generated together.

487 3.2 Bonn

488 The performed analysis and interviews show that the city of Bonn is planning and accelerating
489 the topic of digitalization, in order to remain attractive for citizens and industry in the future, and to
490 increase efficiency in the administration. This can be seen for instance in the project "Digital
491 Administration" as well as within the newly created central coordination office/position for
492 digitalization topics - the "Chief Digital Officer (CDO)". Having already pioneered the open data
493 context, the city of Bonn is still interested in taking part in new developments at an early stage and
494 helping to shape them. This becomes apparent, among other things, in the Smart City test areas in
495 the city.

496 3.3 Dortmund

497 Based on the need to accomplish dynamic and more complex tasks in the context of Smart City /
 498 Community, the availability of real-time data in various areas - above all transport, energy, or
 499 security/safety –is of paramount importance and should be considered an aspired goal.

500 A possible marketing and sales strategy for data, which are not to be assigned to the context of
 501 open data and where a monetary value is expected, has not been yet developed extensively in the
 502 city of Dortmund (such development is expected mainly from the municipal companies). Individual
 503 fee models for certain types of data and information are available, but a holistic cash-flow model
 504 does not exist. Concerning the data, which a city like Dortmund (mainly its municipal companies)
 505 could provide against monetary payments, a continuous balancing of the expenditures for the
 506 supply and marketing with respect to the expected income is to be considered. Under certain
 507 circumstances, other factors are to be taken into account for some data –these factors might influence
 508 a decision against a commercial marketing of the data sets (e.g. social aspects and overall benefits of
 509 critical value for the population and community as a whole). Despite above considerations, the
 510 involved representatives of Dortmund believe to some extent that no uniform fee or cash flow model
 511 will be established across different municipalities and domains.

512 In general, the setup of an Urban Data Space is seen by the city of Dortmund as a helpful overall
 513 construct, which can support the above goals and aspirations in the context of smart city /
 514 community.

515 3.4 Discussion

516 Based on the results of the interviews and belonging analysis, the corresponding
 517 recommendations for action are listed below and explained briefly.

- 518
- 519 - Identification of further strategic fields of action for a comprehensive strategy for an Urban
- 520 Data Space
- 521 - Systematic inventory of municipal data and local ICT infrastructure based on the German
- 522 DIN OUP 91357 ICT reference model for Smart Cities
- 523 - Development of new data sources and raising awareness that urban data is a valuable
- 524 resource
- 525 - Awareness of the presence and potential of crowd-sourced and crowd-sensed data, among
- 526 others for the urban operations and services
- 527 - Raise awareness of the presence and potential of social network data and increase the
- 528 systematic exploitation of social network activity as a strategic resource
- 529 - Involvement of all relevant actors and stakeholders in the construction of an Urban Data
- 530 Space
- 531 - Introduction of a data officer for the Urban Data Space as a dedicated position/office
- 532 - Strengthening or establishing a higher-level coordinating body for digitalization
- 533 - Introduction of a common terminology of the Urban Data Space to facilitate cooperation
- 534 between actors
- 535 - Structuring and strategic development of municipal/urban ICT infrastructures
- 536 - Transfer of the existing municipal technical infrastructure into a standard-based
- 537 infrastructure with open interfaces and formats according to a general ICT reference
- 538 architecture such as DIN SPEC OUP 91357 based on EIP SCC
- 539 - Consideration and integration of the specific local needs and requirements of a municipality
- 540 in the construction of an urban data platform
- 541 - Awareness of possible dependency issues (vendor lock-in) and early actions to avoid such
- 542 potential problems

- 543 - Creation and formulation of an offer that supports and accompanies the installation, data
 544 provisioning, usage and operation of an Urban Data Space
 545 - Usage of existing and provisioning of own open software components in an integrative
 546 manner towards the realization of an Urban Data Space
 547 - Analysis of a large number of potential urban use case based on data utilization
 548

549 In order to address the above recommendation, a general structure of an Urban Data Space is
 550 required. Such a structure is provided in the next chapter of this paper, which deals with the design
 551 of an Urban Data Space.

552 4. Designing the Urban Data Space

553 The technical prerequisite for a functional Urban Data Space is the coherent, coordinated and
 554 networked data and system landscape of all actors, departments and organizations of the involved
 555 municipality.

556 The analysis presented in the previous chapter shows that the data and system landscape in the
 557 municipalities is very fragmented, as well as the associated existing knowledge. It must be
 558 emphasized that the technologies and technical concepts are already existing, both for overcoming
 559 the fragmentation of the data aspects as well as for the hardware and software integration or
 560 orchestration for the purpose of creating a common Urban Data Space. The present legal framework
 561 also offers development opportunities for municipal business models.

562 However, municipalities have so far lacked a holistic concept for the permanent and sustainable
 563 construction of Urban Data Spaces. This chapter presents a practicable technical approach and
 564 advocates for the application of a "standardized, open reference architecture" as a blueprint for the
 565 construction of Urban Data Spaces in German municipalities.

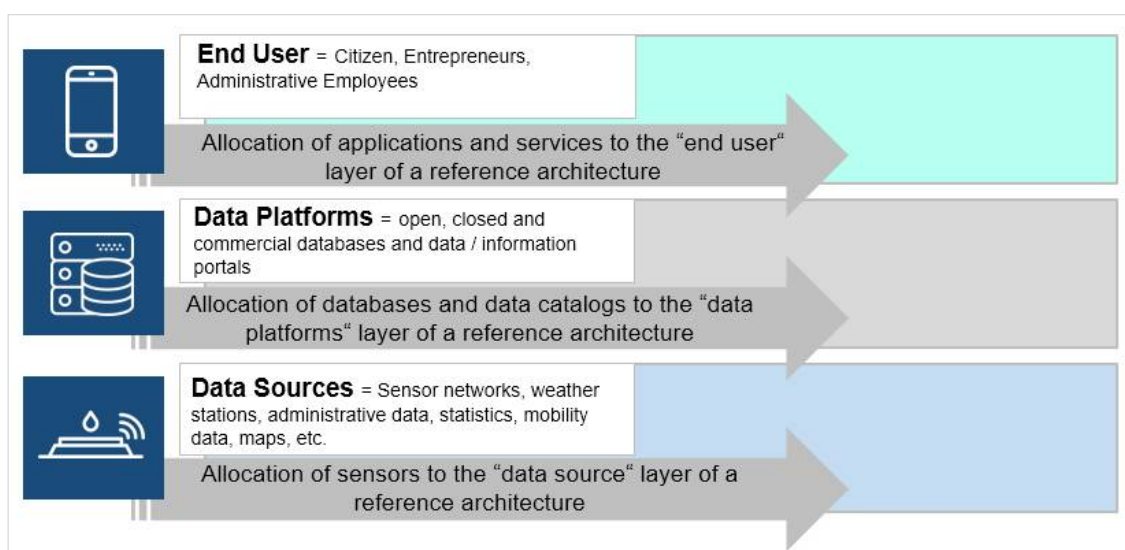

566 An open reference architecture - as described for example in DIN SPEC OUP 91357 - is
 567 characterized by its integrative and modular character. It fulfils principles such as interoperability,
 568 reusability, openness and scalability. These design principles for IT architectures in public
 569 administration have been identified and promoted by SAGA [30] as a key "eGovernment standard"
 570 (since 2002) by the Federal Government's Information and Communication Office in the German
 571 Federal Administration (Bundesverwaltung). These principles are also used in open reference
 572 architectures for smart cities/communities, as in DIN SPEC OUP 91357 [16]. The application of
 573 SAGA also ensures that the selection of technologies is based on transparent criteria and consistent
 574 quality requirements. In addition, we suggest that the ICT components of an Urban Data Space used
 575 in specific implementations of DIN SPEC OUP 91357 should be audited and certified as required by
 576 BSI's [31] security requirements. The compliance to the BSI³ security requirements and the design
 577 principles of SAGA - in the context of DIN SPEC OUP 91357 - ensure the security, resilience and
 578 trustworthiness of the Urban Data Space.

579 The key benefits of this approach to building urban datasets are: 1) the systematic structuring of
 580 existing ICT solutions and datasets along the blueprint image, 2) identifying the gaps in the city's
 581 ICT architecture and the needed actions. At the same time, it becomes visible which systems or
 582 components already exist and how they can be linked and mapped to the blueprint reference
 583 architecture. 3) The openness of the interfaces and formats promotes interoperability as well as the
 584 reuse of components and solutions. Existing legacy systems can be integrated by providing and
 585 interfacing with interoperable interfaces. 4) Existing ICT components from other communities can be
 586 interchanged and reused. 5) A standards based approach with open interfaces and formats promises
 587 enduring, future-proof, high-security ICT solutions. 6) On the basis of the general reference
 588 architecture, it is possible to develop a municipality specific Urban Data Space that fulfils the locally
 589 defined requirements for a concrete municipality in the long term.

590 These benefits of using DIN SPEC OUP 91357 will be discussed in more detail below. The
 591 necessary steps for the establishment of an Urban Data Space are discussed according to the method

³ BSI stands for Bundesamt für Sicherheit in der Informationstechnik/Federal Office for Information Security

592 outlined above. Next, the objectives of the technical approach are formulated and a motivation is
 593 provided for the use of established ICT reference architectures for Smart Cities. Based on this
 594 discussion, the benefits for municipalities are derived and specific technical artefacts required for the
 595 implementation of an Urban Data Spaces are described.

596

597

598

604

605

606

607

608

609

The interviews with actors in the municipalities involved in the studies give a picture of a fragmented technology landscape. This applies to the heterogeneous data sets in the inventory and their availability in the context of an Urban Data Space. In particular, there is a lack of conception and systematic structuring of the existing ICT landscape. Furthermore, the potential difficulties in establishing Urban Data Spaces are not approached in a systematic way, taking into account existing components and ICT systems in the investigated municipalities. Possible steps to deal with the current situation and to enable further development towards an Urban Data Space are listed below. These steps will later be presented separately as recommendations for action and aim at the sustainability of the proposed concepts.

610

611

612

613

614

In order to develop the Urban Data Space sustainably and incrementally, one must begin with the systematic review and inventory of the data space and the mapping of the locally existing technical structure as exemplified in Figure . In particular, it is required to gain a complete picture of the ICT systems in operation, historical databases, as well as the currently available, generated and consumed data through local community services and applications. In addition, the associated interfaces and data formats of all systems must be described and classified accordingly.

615

616

617

618

619

620

621

622

623

624

625

As a result, the aim is to classify the local technical inventory into a general architecture. Our recommendation is to use ICT reference architectures designed especially for smart cities/communities - such as EIP SCC [15], DIN OUP 91357 [16] or the "Triangulum" [32][34][35] and "Espresso" [33][36] reference architectures from the belonging European Horizon 2020 research projects. The use of such reference architectures enables the systematic development of a municipal data and system inventory in the direction of an advanced Urban Data Space, taking into account and integrating the specific needs and requirements of a city/municipality in the construction of an urban data platform. In addition, openness - in terms of open interfaces, open data, data models, and open standards - as the basic principle of an ICT architecture, enables the involvement of all relevant actors in the design and construction of the Urban Data Space. The open concept of a reference architecture composed of many interchangeable modules enables a vibrant and dynamic ecosystem

626 of coexistence across multiple products and companies. The open urban platform is free of so-called
627 "vendor lock-in effects" - which means that its modularity and the interoperable interfaces between
628 the modules greatly reduce and at best prevent dependency on individual manufacturers and
629 operators. The concept enables the participation of a large number and variety of involved actors:
630 the local IT, small and medium-sized enterprises as well as start-ups, large-scale industry, the
631 open-source economy, various initiatives as well as citizens. The concept of an open urban platform
632 enables many initiatives and companies (including SMEs) to set up pilot projects in cooperation with
633 municipalities or economically-linked municipalities, thereby promoting the sustainable
634 development of an Urban Data Space and smart urban scenarios on top.

635 4.2. Technical Goals

636 Along the steps for the establishment of an Urban Data Space, corresponding goals for the
637 technical implementation can be derived. In the first place, a **technical implementation of an Urban
638 Data Space based on a standardized and expandable ICT reference architecture for smart cities /
639 communities is to be developed**. This should be based on open interfaces and open formats. It is
640 also recommended that local authorities expand their available amount of **open data and promote
641 the utilization of open source components**. This will create an ICT ecosystem for Urban Data
642 Spaces that will allow cities and communities to **avoid widespread problems such as vendor
643 lock-in, i.e. dependency on large platform manufacturers, and to ensure competition and data
644 protection**.

645 Existing municipal ICT systems can serve as a basis for creating an Urban Data Space. Existing
646 implementations and artefacts should be captured as components and integrated into the overall
647 technical infrastructure of the Urban Data Space. Missing components should be systematically
648 added to maximize data and information exchange within the urban data platform and provide as
649 many innovative services and offers as possible. In this case, the used ICT components are to be
650 regarded as part of a security-relevant infrastructure and to be evaluated for productive operation in
651 accordance with the BSI cyber-security requirements as well as to be examined for potential
652 vulnerabilities.

653 The use of reference architectures for municipal ICT infrastructures is already happening on a
654 broad scale. Many initiatives for smart cities/communities develop solutions based on specific
655 reference models. Especially at the European level, various projects and collaboration initiatives
656 (such as Espresso, Triangulum or STREETLIFE) have developed municipal solutions based on
657 reference architectures. For example, the use of ICT reference architectures is also endorsed in the
658 Smart City Charter of the Federal Institute for Research on Building, Urban Affairs and Spatial
659 Development (BBSR), which has already been cited several times in this work. In addition, the
660 European Innovation Partnership on Smart Cities and Communities (EIP SCC) at the European level
661 and DIN SPEC OUP 91357 in Germany constitute two important initiatives that define a so-called
662 "open urban platform". **We recommend the construction of an Urban Data Space based on ICT
663 concepts in the sense of a reference architecture as elaborated in EIP SCC and DIN SPEC OUP
664 91357.**

665 4.3. DIN SPEC 91357 „Reference Architecture Model Open Urban Platform“

666 In the following, we will go into more detail about the DIN SPEC OUP. The DIN specification
667 (SPEC 91357) "Reference Architecture Model Open Urban Platform" is the version of the EIP SCC
668 reference architecture adapted for Germany. The rough structure of the DIN SPEC OUP and
669 according to the EIP SCC ICT reference architecture is shown in Figure 3. Since both activities
670 operate on an international level, DIN SPEC OUP has the potential to be considered within the
671 framework of ISO for international standardization.

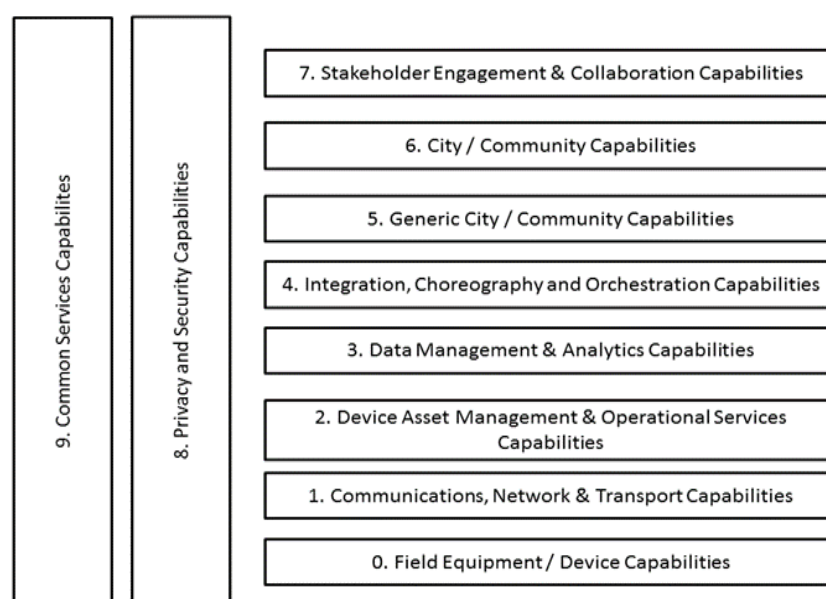

672 The DIN OUP ICT reference architecture is divided into eight layers and two columns. Each of
 673 these layers/columns has a number of capabilities that are to be realized as part of the layer/column.
 674 Detailed lists of the performance characteristics of each layer can be found in the corresponding DIN
 675 specification and the European document on the EIP SCC reference architecture. The lowest layer (**0.**
 676 **Field Equipment/Device Capabilities**) contains most of the data sources within a community. In
 677 particular, various sensors and measuring stations are located there, which generate data for the
 678 upper layers of the reference architecture. This is the next layer (**1. Communications, Network &**
 679 **Transport Capabilities**), which includes the networking of individual devices over a
 680 communication infrastructure and stands for the communication network (telecom network or
 681 Internet) and the transfer of data from the lower layer to the data platforms in the upper layers.

682 The 0-layer devices and the first layer communication infrastructure are controlled by protocols
 683 and software modules included in the second layer called **Device Asset Management &**
 684 **Operational Services Capabilities**.

685 Based on this basic infrastructure, the data sources are networked with the data platforms in the
 686 third layer (**3. Data Management & Analytics Capabilities**). This layer includes data management
 687 systems, databases, open data portals, and cloud platforms that store or properly describe the data
 688 from the sources (e.g. meta-data catalogs such as CKAN) and provide the data to other services and
 689 applications in the urban and municipal context. The data is stored according to its validity (for
 690 example, temporary sensor data from the Internet of Things) or versioned and archived according to
 691 pre-specified rules. Additionally, in this layer, the data is analysed and correlated. Moreover, the
 692 data can also be provided on the basis of further processing, for example on the basis of statistical
 693 algorithms or on the basis of processing in the sense of machine learning.

694 The layer (**4. Integration, Choreography and Orchestration Capabilities**) contains various
 695 types of services that offer innovative use cases within a community through the interplay and use
 696 of different data and information from the underlying layers.

697 The following layers **5. Generic City / Community Capabilities** and **6. City / Community**
 698 **Capabilities** stand for the various urban processes, everyday activities and general innovations that
 699 are made possible on the basis of DIN OUP's ICT processes. Examples include the potential for
 700 improving administrative processes and optimizing public transport routes for improved mobility
 701 within a municipality.

702

703

Figure 3. An ICT reference architecture for Smart Cities based on EIP SCC and DIN OUP.

704 The seventh layer in Figure 3 deals with the interactions - in the technical, social and economic
 705 sense - with the users of the application scenarios and the associated integrative solutions. This is the

706 layer in which the benefits of an Urban Data Space based on DIN OUP become real. In the
707 corresponding applications (such as smartphone apps, information portals, issue management
708 systems, collaboration systems etc.) added value is created for the administration and also for the
709 citizens of a municipality

710 The two pillars on the left side of the Reference Model are responsible for privacy and security
711 **(8. Privacy and Security Capabilities)** and overall system management **(9. Common Services**
712 **Capabilities)** for the emerging comprehensive integrative ICT solutions within an Urban Data
713 Space. They cover several layers and ensure IT security and the proper operation of the Urban Data
714 Space.

715 Finally, it should be noted that the exchange of data and information between the components
716 of the Urban Data Space should be determined by the use of standardized communication protocols
717 and data models. This requirement is explicitly emphasized at European and German level and is
718 the basic prerequisite for the implementation of an open, inclusive, extensible and structured Urban
719 Data Space.

720 4.4. Advantages for Cities and Municipalities

721 The use of ICT reference architectures described above has many advantages for municipalities:

722 (1) The openness of the architecture - as well as the use of open standards, interfaces, formats
723 and data models - encourages the municipality to reduce dependency on individual manufacturers
724 and operators and thus reduce the risk of vendor lock-in. Vendor lock-in is generally understood as
725 the full dependency of a customer on a particular ICT provider, manufacturer or infrastructure
726 manager. A vendor lock-in arises when, for example, service providers build on proprietary (that is,
727 on non-open and not freely available) interfaces and data formats and thus sell a closed solution as a
728 complete package, for example to municipalities. Such a complete solution can extend over several
729 layers of the presented reference architectures. In such a case, the maintenance – i.e. the bug fixes,
730 but also the updates (software and hardware updates) – is completely in the hands of the
731 corresponding provider and cause permanent costs due to a dependency of the community on the
732 provider with no chance of improving the situation. Such a situation violates the "open" platform
733 thinking of an Urban Data Space and may make it difficult or even deny regional SMEs access to a
734 community's ICT ecosystem. This situation is also detrimental to a municipality's claim to
735 sustainability. Closed commercial platform solutions can also jeopardize the sovereignty of
736 communities over their data and restrict or prevent free access to urban data. In the event of a
737 vendor lock-in, some data may become the property of the relevant platform operator and may only
738 be accessible at a corresponding cost. This would give municipalities limited opportunities to
739 participate in the use and refinement of their own data.

740 It should be stated that the realization of Urban Data Spaces using standardized reference
741 architectures with open interfaces and formats - in particular DIN OUP 91357 - builds up a (2)
742 support of local self-government and the sovereignty of a municipality over their data - this point
743 can be seen as a significant advantage of the presented technical approach.

744 Based on this consideration, there are further obvious advantages for the municipalities:

745 (3) Local SMEs can implement specific municipal requirements - the openness of the Urban
746 Data Space makes it possible for local SMEs to be assigned specific tasks and developments at any
747 time.

748 (4) Easy integration of digital participation forms and initiatives - this point arises from the
749 openness and the systematic expandability of the Urban Data Space. In particular, the use of open
750 source solutions as well as the consideration of specific needs of the society is possible.

751 (5) The integrative approach supports a consistent cyber-security concept - the openness of the
752 used interfaces makes it easy for different actors to perform certain types of tests that assess and
753 improve the security of the utilized components.

754 The openness of the architecture enables institutions such as the Federal Office for Information
755 Security (BSI) and related certification bodies to assess the security of an Urban Data Space and to

756 demand corresponding changes that increase cyber-security. In addition, it is possible to use
757 standardized "test suites" that verify and check compliance and security - functional security as well
758 as hacker defense capabilities examined by penetration tests - of the IT systems to be deployed.

759 From the discussions so far, there is automatically a (6) location advantage through an
760 improved ICT infrastructure as well as improved (7) interoperability and the possibility of using
761 open interfaces. In addition, an Urban Data Space based on DIN OUP 91357 promotes the use of (8)
762 standardized components based on reference architectures.

763 Other benefits derived from the envisaged Urban Data Space are already formulated indirectly
764 - notably through the avoidance of vendor lock-in, the involvement of local SMEs, the use of open
765 standards, and improved interoperability and security. All these aspects help a municipality in (9)
766 promoting its general sustainability and (10) preserving its possibilities to act in an independent way
767 when it comes to data related topics.

768 These benefits are important pillars for the digitalization and development of local
769 communities, and for the exploitation of the data resources that can emerge in an urban environment
770 and can contribute to improving the quality of life and work of citizens. In the following chapter
771 another extremely important aspect is emphasized, namely the data governance procedure for an
772 Urban Data Space that support in achieving data sovereignty for key stakeholders in emerging UDS.

773 5. Data Governance & Data Sovereignty

774 The terms urban data governance and sovereignty are strongly related to identifying the actors
775 involved in the management, provisioning [20] and utilization of urban data , as well as the required
776 communication and interactions among these actors/stakeholders. On one hand, it is required to
777 develop guidelines determining the responsible stakeholders for the belonging processes of data
778 provisioning and management, while on the other hand the variety of existing regulations and rules,
779 which define the way urban data is to be handled, should be considered. Hence, the required
780 processes for data handling should be implemented by the identified stakeholders and monitored
781 through appropriate structures in order to ensure compliance to belonging regulations. Such
782 structures would also enable the data owners to keep and evolve their sovereignty over the
783 provided data.

784 An aspect of paramount importance for urban data governance is constituted by the need for a
785 sustainable and adequate organization for controlling data originating from urban environments,
786 thereby paying special attention to the needs of the community, the public administration and the
787 municipal companies. This implies that organizational setups, guidelines and processes must be
788 correspondingly derived and combined as to interplay successfully. Public institutions collect vast
789 amounts of data, which is a valuable resource for the development of innovative digital
790 services/applications, urban optimization and improved policy-making processes.

791 The EU has already specified a number of legislative measures to open up public databases
792 across the European Union as an important source of information for the data economy. Directive
793 2003/98/EC on the re-use of public sector information has created an EU-wide framework that
794 facilitates the cross-border provisioning and utilization of publicly funded data and constitutes a
795 viable asset for the development of pan-European data based products.

796 For data governance in general, it should be clearly defined which roles are relevant for the
797 provisioning and processing of data, and how these roles are to be embedded in the decision-making
798 process. The decision-making processes address aspects like data quality management, data access
799 management, general data management and lifecycle management [37]. In addition, there is the key
800 task of managing the meta-data for the datasets in an urban environment, which is also important in
801 the context of data sovereignty and quality. Considering the above statements, different approaches
802 can be derived for realizing data governance in Urban Data Spaces. In general, very often the
803 so-called RACI notation is utilized to implement governance structures. RACI is an abbreviation for
804 responsible, accountable, consulted, informed [38]. Correspondingly, when defining the roles for
805 urban data governance in a particular context, the definitions should be worked out in terms of the
806 four RACI characteristics for the decision-making area in question.

807 In the above described context, the following five roles can be defined (based on recent EU level
808 research activities [21]), which are described here based on high level considerations: 1) **Data**
809 **Committee** - The Data Committee is a decision body with the key role to define and coordinate
810 directives and decisions. If problems arise within an Urban Data Space, the Data Committee is the
811 body which is expected to work out solutions and track their implementation. 2) **Governance**
812 **Officer** - The Governance Officer is part of the Data Committee and disseminates, promotes and
813 monitors the policies and decisions within the organization. He acts as the central coordinator for a
814 specific Urban Data Space within the organization in question. 3) **Data Owner** - The Data Owner is
815 essentially in charge of one or more datasets from a business perspective. The responsibility relates
816 to various topics such as the framework and regulations for further data set usage or to the quality of
817 the data. In addition, the Data Owner takes care of the legal requirements and is responsible for the
818 aspects of licensing and commercial cost/price of the data. 4) **Data Steward** - The Data Steward bears
819 the responsibility for implementing the requirements of the Data Owner, e.g. proper (meta-)data
820 management. In general, the Data Steward represents the link to the technical users of a dataset. 5)
821 **Technology Steward** - The Technology Steward manages the technology platform in place for all the
822 data of a stakeholder. The Technology Steward has to guarantee that the selected technological stack
823 is sufficient to fulfil the data quality requirements. In addition, the required technical support
824 includes aspects of data backup, data security and the (meta-)data archiving.

825 Regarding open data, the PSI (Directive 2003/98/EC) directive clearly states that data
826 originating from public institutions should be freely published and made available to the society as
827 open data. Thereby, Open Data Platforms support this requirement by offering the means for
828 publishing the data sets and handling the belonging meta-data. Different roles are specified within
829 each data portal/platform with data user, data provider and operator being some of the common
830 roles within today's open data portals. Beyond governmental institutions, municipal companies
831 generate interesting types and amounts of data that can enable useful urban applications and
832 services. However, municipal companies are mostly not solely publicly owned but also hold private
833 shares and aim at achieving business goals which might also be based on selling data. Hence, in
834 these cases only particular data sets would be made publicly available in different forms, while
835 others would be offered in exchange for appropriate assets (e.g. money or services). Therefore, it is of
836 paramount importance to emphasize the importance of standards when publishing data sets as open
837 data. For instance, some initiatives [39] require data sets to have the following properties, which are
838 also listed as key principles within the open data community: complete, primary, timely, accessible,
839 machine processable, non-discriminatory, non-proprietary, and license-free - such characteristics
840 can be to some extent achieved by using proper technical standards such as Linked Data, RDF, CSV,
841 DCAT and XML. Furthermore, the data requires many additional interactions and discussions with
842 those responsible for the data sets within the publishing institutions.

843 6. Conclusion & Future Work

844 This paper presented the results of a recent study that was conducted with a number of German
845 municipalities/cities. Thereby, the need was identified to setup and create so-called Urban Data
846 Spaces within cities and municipalities in order to reveal the vast potential offered by urban data.
847 Building on the recommendations emerging from the study, the authors classify the various types of
848 urban data and elaborate on the characteristics of the identified data classes thereby relating to legal
849 and monetary aspects.

850 After establishing a definition of an Urban Data Space, the concept is analyzed in detail and a
851 proposition for setting up an Urban Data Space is worked out. The authors propose to setup Urban
852 Data Spaces based on emerging standards from the area of ICT reference architectures for Smart
853 Cities, such as DIN SPEC 91357 "Open Urban Platform" and EIP SCC. Thereby, the paper presents
854 the transformation steps required from municipal perspective (especially in the German context) to
855 successfully implement an Urban Data Space. Furthermore, the paper elaborates on vital aspects
856 such as data governance and data sovereignty and shows how these would be realized within the
857 proposed approach.

858 With respect to future work, we aim at continuing our standardization work at various relevant
 859 standardization bodies and relating to various domains and use cases. In addition, a reference
 860 implementation of standard open source components for Urban Data Spaces is envisioned, which
 861 would allow for quickly setting up an Urban Data Space and evaluating different scenarios and
 862 business models. Finally, the idea of quality assurance for ICT components within Urban Data
 863 Spaces is of paramount importance and will be pursued on research level.

864 **Acknowledgments:** This work has been partially supported by H2020-Triangulum project (GRANT
 865 AGREEMENT No. 646578) and by the German BMBF project "Urban Data Spaces"
