Abstract: Preventing muscle wasting in certain chronic diseases including cancer is an ongoing challenge. Studies have shown that polyphenols derived from fruits and vegetables show promise in reducing muscle loss in cellular and animal models of muscle wasting. We hypothesized that polyphenols derived from plum (Prunus domestica) could have anabolic and anti-catabolic benefits on skeletal muscle. The effects of a polyphenol-enriched plum extract (PE60) were evaluated in vitro on C2C12 and Colon-26 cancer cells. Treatment of myocytes with plum extract increased the cell size by ~3-fold (p<0.05) and stimulated myoblast differentiation by ~2-fold (p<0.05). Plum extract induced total protein synthesis by ~50% (p<0.05), reduced serum deprivation-induced total protein degradation by ~30% (p<0.05), and increased expression of IGF-1 by ~2-fold (p<0.05). Plum extract also reduced TNFα-induced NFκB activation by 80% (p<0.05) in A549/NFkB-luc cells. In addition, plum extract inhibited growth of Colon-26 cancer cells, and attenuated cytotoxicity in C2C12 myoblasts induced by soluble factors released from Colon-26 cells. In conclusion, our data suggest that plum extract may have pluripotent health benefits on muscle based on its demonstrated ability to promote myogenesis, stimulate muscle protein synthesis, and inhibit protein degradation. It also appears to protect muscle cell from tumor-induced cytotoxicity.

Keywords: Cachexia, Plum, Cancer, Muscle wasting, Myoblasts, Protein synthesis

1. Introduction

Skeletal muscle weakness and wasting, which is also referred as cachexia, is a major clinical problem for advanced cancer patients [1]. Warren in 1932 described cachexia as the most common cause of death across a variety of cancers in a post mortem study of 500 patients [2]. The term “Cachexia” is derived from the Greek words “kakos” and “hexis,” meaning “bad condition.” It is a multi-organ syndrome associated with and characterized by at least 5% body weight loss due to muscle and adipose tissue wasting [3]. Cancer cachexia is a multifactorial syndrome that is common in advanced malignancy occurring in 80% of patients, which cannot be reversed by nutritional support and leads to significant function deficits [4], and which is responsible for an estimated 20% of cancer-related deaths [5].
Colorectal cancer (CRC) patients are often presented with cachexia syndrome, which is a major contributor to colorectal cancer-related morbidity and mortality [4-8]. About 35 to 60% of CRC patients show some degree of muscle wasting and 28% lose >5% of their body weight in the 6 months preceding diagnosis [9]. Blocking muscle wasting can prolong life even in the absence of effects on tumor growth [10].

Oxidative stress through activating initial steps in protein degradation via the ubiquitin-proteasome pathway, and activation of caspases, contributes to muscular atrophy [11-13]. In addition, inflammation also leads to muscle atrophy and this is mediated through cytokine (e.g. tumor necrosis factor α (TNFα), interleukin-6 (IL-6), and interferon γ (IFNγ)) induced activation of the nuclear factor κB (NF-κB) pathway [14].

Recent studies have shown that polyphenol-rich plant extracts prevent oxidative stress, reduce inflammation, and help reduce muscle atrophy. We have previously shown that curcumin treatment attenuated muscle wasting in cancer cachectic mice [15]. Supplementation with red grape polyphenols mitigated muscular atrophy in transforming growth factor (TGF) mice, by acting on mitochondria function and by caspase activation [16]. Grape seed extract supplementation effectively prevented muscle wasting in IL10-knock out mice [17]. Green tea polyphenol, catechins, protected normal and dystrophic muscle cells from oxidative damage [18]. Epigallocatechin-3-gallate (EGCG) supplementation preserved muscle in sarcopenic rats [19] and attenuated skeletal muscle atrophy caused by experimentally induced cancer cachexia in in mice [20]. More recently ursolic acid has been shown to increase muscle mass in mice exhibiting fasting-induced muscle atrophy [21] and it has also increased muscle mass, fast and slow fiber size, grip strength, and exercise capacity in mice with diet-induced obesity [22]. These observations clearly suggest that intake of polyphenols can be beneficial in preserving muscle mass.

The common plum (Prunus domestica) is well known to be rich in polyphenols and contains unique phytonutrients called neohesperidin and chlorogenic acid which have high antioxidant activities. Among functional foods, plums are also considered “super foods” since their consumption has been associated with the decrease in chronic degenerative diseases and circulatory and digestive issues [23]. Dried plums have been shown to reduce symptoms of arthritis in an inflammation model [24]. These effects are attributed to their high polyphenolic composition and related high antioxidant activity [25]. Plums have several health benefits and studies have found that plums also initiate anti-cancer mechanisms that may help prevent the growth of cancerous cells and tumors [26-28].

In addition, plums have been extensively studied for their effects on bone health [29, 30]. Plums contain caffeic acid (the polyphenol component of neochlorogenic and chlorogenic acids) and rutin, which have been shown to inhibit the deterioration of bone tissues and prevent diseases such as osteoporosis in postmenopausal women [31]. Research has also shown that regular consumption of dried plums helps in the restoration of bone density lost to aging [32].

Formation of bone and much of the skeletal tissues is derived from the proliferation and differentiation of skeletal stem cells. As dried plum was found to be a potent regulator of bone health, it is possible that plum and its associated polyphenols may have benefits on other cells of musculoskeletal system. Thus, in the present study, we sought to investigate the effect of a polyphenol-enriched plum extract on muscle cell growth and differentiation, and on muscle protein synthesis and degradation in vitro. In addition, we explored the effect of plum extract on inflammation as well as studied its effect on colon cancer cells.

2. Materials and Methods

2.1. Materials:

Dulbecco’s modified Eagle’s medium (DMEM), fetal bovine serum (FBS), horse serum, and Penicillin-Streptomycin solution were purchased from Gibco-Thermo-Fisher Scientific (Grand Island, NY). L-[2,3,4,5,6-3H] Phenylalanine and L-[Ring-3, 5-3H]-Tyrosine was purchased from Perkin-Elmer (Waltham, MA). Prune extract-60% enriched polyphenol extract (PE60) was purchased...
from PL Thomas (Morristown, New Jersey). All other chemicals were of reagent grade, and were purchased from Sigma Chemical Co. (St. Louis, MO).

2.2. Composition of the PE60-plum extract

Free gallic acid, 3-cholorogenic acid, rutin, free quercetin, and proanthocyanidins were determined with an Agilent Technologies (Wilmington, DE, USA) Model 1200 HPLC System equipped with a Model G1311A quaternary pump, Model G1322A vacuum degasser, Model G1329A autosampler, Model G1316A thermostatted column compartment, a Model G1315B diode array detector, and a Chem Station data processor. The separations were performed with a YMC-Pack ODS-AQ analytical column (4.6 x 250 mm, 5 µm, P/N AQ12S05-2546WT, Waters Corporation, Milford, MA, USA), using mobile phase A = 1000/100 (v/v) 0.05 M KH2PO4, pH 2.9/acetonitrile, and mobile phase B = 200/800 (v/v) Milli-Q Plus water/acetonitrile, a column temperature of 40 °C, an injection volume of 5 µL, and the analytes were quantified at signals of 280 nm/590 nm (for gallic acid and the proanthocyanidins), 330 nm/590 nm (for 3-chlorogenic acid), and 375 nm/590 nm (for rutin and quercetin). The elution program was 0% mobile phase B from 0 to 5 minutes, 0 to 60% (linear gradient) mobile phase B from 5 to 35 minutes, 100% mobile phase B from 35 to 40 minutes, and 0% mobile phase B from 40 to 55 minutes (end). The PE-60 extract was prepared for analysis by stirring (at room temperature for fifteen minutes) 0.250 g in 100 mL of 50/50 (v/v) 0.05 M citric acid/methanol. The determinations were calibrated with standard solutions of gallic acid, 3-cholorogenic acid, rutin hydrate, and quercetin dihydrate (all obtained from Sigma-Aldrich, St. Louis, MO, USA), also prepared in the citric acid/methanol medium. The proanthocyanidin content was estimated by peak area proportionation vs. the corresponding peak areas (at 280 nm/590 nm) of grapeseed extracts (from Kikkoman, Polyphenolics, and Seppic) of known (i.e., label claim) proanthocyanidin content, included in the analysis. The anthocyanin concentration was estimated by a published colorimetric method [33].

2.3. Characterization of anti-oxidation capacity of the plum extract

The PE60 (Lot PE6009-1601) extract was dissolved in water and then centrifuged at 1500 x g for 10 minutes to remove any insoluble material. The dissolved material was sterile filtered, and the filtrate was assayed for total polyphenols by the Folin Ciocalteu method [34], for total flavonoids by the AlCl3 complexation method [35], for anti-oxidant activity by the DPPH assay [36], and for oxygen scavenging activity by the ABTS assay [37], as described.

2.4. Cell culture

C2C12 cell line (mouse myoblasts) were obtained from American Type Culture Collection (Manassas, VA). The undifferentiated cells were grown in Dulbecco’s modified Eagle’s medium (DMEM, 4.5 mg/ml glucose) supplemented with 10% heat-inactivated fetal calf serum at 37°C in the presence of 5% CO2. The myoblasts were differentiated into myotubes by culturing them into differentiation medium, consisting of DMEM supplemented with 5% heat-inactivated horse serum for 5 days.

2.5. Determination of C2C12 myoblast cell size

Muscles cells were grown in a 96-well plate for 24 hours in 100 µl complete media. Cells were then treated with 0, 50, 100, 150, 200 µg/ml of extract for 48 hours, by changing the media after 24 hours of incubation. After incubations, the cells were observed under a microscope and pictures (100 x magnification) were taken using a Nikon microscope with calibrated objectives. The size of cells was determined using Element-BR software.
2.5. Assaying C2C12 myoblast differentiation

Muscle cells were initially cultured in a 96-well plate for 24 hours in 100 µl complete media. Cells were then incubated with 0, 50, 100, 200 µg/ml plum extract for 5 days and the medium containing corresponding concentration of plum extract was changed every 24 hours. After treatment, the cells were washed once with PBS, and then fixed with cold 4% paraformaldehyde for 10 min on ice. The cells were washed 3 times with PBS, and the monolayer was treated with blocking solution containing 2% albumin. The cells were then incubated with anti-myosin antibody at room temperature for 2 hours. Cell were washed again and then incubated with anti-mouse Alexa-488 antibody (Abcam, Cambridge, MA) for two hours. Cells were washed again 3 times with PBS, and the nuclei were stained briefly with Hoechst 33342 dye (1:2000 dilution). Pictures were taken at 200 x magnification using a Nikon Fluorescent Microscope. Myotubes were defined as myosin positive cells with 2 or more fused nuclei.

2.6. Protein synthesis in cultured C2C12 myotubules

C2C12 cells (375,000) were initially plated on a 12-well tissue culture plate that was initially coated with 2% gelatin. Cells were differentiated for 5 days in 5% horse serum (media was changed every 2 days), and then starved for 30 min by replacing the media with 1 ml PBS. The cells were then treated with 0, 50, 100, and 200 µg/ml of plum extract in PBS, spiked with [3H] phenylalanine (1µCi/well), and incubated for 2 hr at 37°C. The reaction was stopped by placing the plates on ice. Wells were washed 2 times with DPBS-media containing 2 mM cold phenylalanine. 1 ml of 20% cold TCA solution was added to each well, and plates were incubated on ice for 1 hr for protein precipitation. Wells were washed 2 times with cold TCA, and then the precipitated proteins were dissolved in 0.5 ml of 0.5N NaOH containing 0.2% Triton X100 overnight in a refrigerator. An aliquot (5 µl) of the NaOH solubilized material was used for protein determination, and the rest of the dissolved proteins were mixed with scintillation fluid and counted. Data is computed as cpm/mg of proteins and then % change over control is calculated.

2.7. Protein degradation in C1C12 myotubules

C2C12 myoblasts were cultured and differentiated as described above. Cells were then labelled with [3H] Tyrosine 1µCi/1mL in serum free-DMEM (SF-DMEM) for 24 hrs. The unincorporated [3H] Tyrosine was removed by washing the cell monolayer three times with SF-DMEM containing 50 µM cycloheximide (protein synthesis inhibitor) and 2 mM non-labelled Tyrosine. Proteolysis was induced by serum deprivation for 48 hours in the presence or absence of 50, 100, 200 µg/ml of plum extract in serum-free DMEM containing 50 µM cycloheximide. The extent of protein degradation was assayed by monitoring release of radioactive tyrosine in the media after 48 hrs of incubation and was expressed as protein degradation in comparison to control (normalized to 100%).

2.8. Determination of Insulin-like Growth Factor-1 (IGF-1) expression

Total RNA was extracted from C2C12 myotubules with RNeasy Plus Universal Mini Kit (Qiagen, Hilden, Germany) according to the manufacturer’s instructions. The concentration and purity of RNA was determined by measuring the absorbance in a Nano drop spectrophotometer. RT2 First Strand Kit from Qiagen (Qiagen, Hilden, Germany) was used to synthesize first strand complementary DNA (cDNA). The gene expression levels were analyzed by Quantitative real-time RT-PCR conducted on the Bio-Rad CFX-96 Real-Time PCR System using RT2 SYBR Green Master mix (Bio-Rad Laboratories, Hercules, CA). The primers (IGF: forward primer GGACCAGAGACCTTGTCCGGGG and reverse primer, AGCTCAAGAACATCCCGCCTAGA; GAPDH: forward primer ATCCCATCACCATCTTCCAG and reverse primer...
CCATCACGCCACAGTTTCC) were designed. Hot-Start DNA Taq Polymerase was activated by heating at 95°C for 10 min, and real time PCR was conducted for 40 cycles (15 s for 95°C, 1 min for 60°C). All results were obtained from at least three independent biological repeats. Data were analyzed using the ΔΔCT method. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) genes were used as house-keeping genes for expression calculation.

2.9. Determination of NFkB activation

A549/NFkB-luc cells (Panomics Catalog No. RC0002) at 3 x 10^5/well were seeded in 1 ml of Initial Growth Media (Dulbecco’s Modified Eagle’s medium containing 10% FBS and 1% Pen-Strep) in a 12-well plate. The cells were incubated in a humidified incubator at 37°C and 5% CO₂ for 24 hours to allow cells to recover and attach. After washing the cells once with serum-free media containing 1% Pen-Strep, 1 ml of this media was added to each well. Cells were pretreated with varying concentrations of plum extracts for 1 hr at 37°C and 5% CO₂, and then TNFα was added to achieve a final concentration of 2 ng/mL to all wells except control untreated cells. The cells were incubated in a humidified incubator at 37 °C and 5% CO₂ for 6 hours. After treatment, the media was carefully removed. Cells were washed with PBS once, added then lysed by 100 µl of 1X lysis buffer. Assay for luciferase activity was performed according to assay manufacturer’s (Promega P/N E1500) recommendations. The average RLU values were calculated and corrected for baseline quenching for each set of triplicate wells, using Winglow software and Microsoft Excel. The data is reported as the relative percent inhibition of TNFα mediated NFkB activation on A549 cells.

2.10. Effect of plum extract on Colon-26 proliferation and its’ soluble factor induced cytotoxicity on C2C12 myotubules:

Effect of plum extract on Colon-26 cell proliferation was assayed using a Water-Soluble Tetrazolium-1 (WST-1) (Talkara, Shiga, Japan) assay as described previously [38]. To determine the effects of soluble factors released from Colon-26 on C2C12 myotubules, conditioned media from Colon-26 culture was collected after 24 hrs of cultivation. The media was centrifuged at 2500 x g for 20 minutes to remove cellular material. The clear supernatant (conditioned media) was diluted 1:10 with normal complete media. The C2C12 differentiated myoblasts were then treated with normal complete medium or with Colon-26 conditioned medium with or without 50 µg/ml plum extract. The cell viability was assayed using a WST-1 assay. Control cells were subjected to equal amounts of non-conditioned media.

2.11. Data Analysis

The data is expressed as mean ± SD for at least 3 replicates. All comparisons were made by one-way ANOVA with Tukey’s -HSD-post-hoc test using SPSS Statistics 20 software. All significant differences are reported at P<0.05 and indicated by “*”.

3. Results

3.1. Characterization of PE60 plum extract composition and anti-oxidation properties

As shown in Table 1, the major components identified in the polyphenol-enriched PE60 plum extract are proanthocyanidins, along with minor components such as anthocyanidins, 3-chlorogenic acid, rutin, quercetin (free), and gallic acid (free). The PE60 was also characterized by determining total phenolic content (TPC), total flavonoid content (TFC), anti-oxidant activity (DPPH assay) and oxygen scavenging activity (ABTS). The data in Table 2 shows that the content of TPC was in the same range as reported by the commercial vendor (60%). The data indicate that the PE60 contained TPC in range 525 – 575 mg/g of dry extract.
The TFC was in 480 - 560 mg/g dry weight range. The anti-oxidation effects as determined by inhibition of DPPH oxidation and ABTS assay ranged from 3280 - 3460 and 4000 – 4500 μM Trolox equivalents/g, respectively.

Table 1: Characterization of composition of PE60-plum extract

Table 2: Characterization of anti-oxidation properties of PE60-Plum Extract

3.2. Effect of PE60 plum extract on C2C12 myoblast size and differentiation

Plum extract had no cytotoxic effect on myoblast when used even at a high dose of 250 μg/ml (data not shown). It is evident from images that plum extract has some effect on cell proliferation; however, it was interesting to note that the plum extract increased the size of undifferentiated myoblasts in a dose-dependent manner (Figure 1a). The size of myoblast increased ~2-fold (p<0.05) after treating cells with 50 μg/ml of plum extract when compared to that of untreated-control cells. Increase in myoblast size plateaued to a maximum increase of 3-fold at 200 μg/ml concentration (Figure 1b). Effect of plum extract was also assessed on myoblast differentiation. Figure 2a indicates that the plum extract stimulated differentiation of myoblast in a dose-dependent manner using expression of myosin heavy chain as a marker for differentiation. The number of myotubes formed resulting from fusion of differentiated cells was increased by 2-fold in cells treated with 100 μg/ml plum extract (p<0.05) and by 3-fold at 200 μg/ml (p<0.05) compared to that of control cells (Figure 2b).

(a) The representative pictures of myoblast (100 X magnified images) taken by a Nikon Microscope. The bar represents a length of 500 μm. (b) The size of myoblast was determined using Element-BR software as described in “Materials and Methods”. The data are expressed as mean ± SD for at least 3 experiments. All comparisons were made to control (untreated cells) by one-way ANOVA and the significant differences are reported at * p<0.05.
3.3. Effect of PE60 plum extract on myotubule protein synthesis

Plum extract showed almost a linear increase in $[^3]H$ phenylalanine incorporation into proteins in a dose dependent manner in C2C12 myotubules (Figure 3). A dose of 200 $\mu$g/ml of plum extract caused a significant 50% increase in protein synthesis ($p<0.05$).

3.4. Effect of PE60 plum extract on myotubules protein degradation

We also examined if plum extract could reduce myotubule protein degradation induced by serum starvation. Figure 4 revealed that plum extract did inhibit protein degradation in a dose-dependent manner, and at a dose of 200 $\mu$g/ml significantly inhibited protein degradation by 30% ($p<0.05$).
3.5. Effect of PE60 plum extract on IGF-1 expression in myotubes

Expression of IGF-1 mRNA in C2C12 myotubes upon treatment with plum extract is shown in Figure 5. Compared to that of untreated cells, low concentration of plum extract (50 μg/ml) has no significant effect on IGF-1 mRNA expression; however, it significantly stimulated IGF-1 expression when cells were treated at a higher dose (100 or 200 μg/ml) plum extract.

Total RNA was extracted from C2C12 myotubes treated with various concentrations of plum extract and compared to untreated control. All results were obtained from at least three independent biological repeats. Data were analyzed using the ΔΔCT method. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) genes were used as house-keeping genes for expression calculation.

3.6. Anti-inflammatory effect of PE60 plum extract in vitro

We evaluated the anti-inflammatory activity of plum extract by assessing its effect on TNF-α-induced NFkB activation where the activity was measured in terms of luciferase activity of NFkB reporter system assay. Plum extract inhibited NFkB activation in a dose dependent manner (Figure 6). A dose response assay indicated that ~40% inhibition (p<0.05) of TNF-α-mediated NFkB
activation was achieved at 25 µg/ml plum extract, and >80% inhibition (p<0.05) of TNF-α-mediated NFκB activation was achieved at 50 µg/ml plum extract.

Figure 6: Effects of plum extract on NFκB activation
The effect of plum extract on TNFα-mediated NFκB activation was measured in the A549/NFκB-luc reporter stable cell line. Activity was measured in terms of luciferase activity. The data are reported as the relative percent inhibition of TNFα-mediated NFκB activation. The data are expressed as mean ± SD for at least 3 experiments. All comparisons were made to control (untreated cells) by one-way ANOVA and significant differences are reported at *p<0.05.

3.7. Effect of PE60 plum extract on Colon-26 mouse adenocarcinoma cell line
When Colon-26 cells were treated with plum extract, the cells viability was reduced in a dose-dependent manner reaching ~80% reduction (p<0.05) at 150 µg/ml. Upon further increasing the concentration of plum extract, the cell viability was further reduced 90% (p<0.05) at 200 µg/ml (Figure 7).

Figure 7: Effect of plum extract on Colon-26 adenocarcinoma cells
Data were calculated as % inhibition of cell growth in response to various concentrations of plum extract. The data are expressed as mean ± SD for at least 3 replicates. All comparisons were made to control (untreated cells) by one-way ANOVA and the significant differences are reported at *p<0.05.
Mouse derived Colon-26 adenocarcinoma cells are known to induce muscle wasting in rodents [39]. The effect of these circulating soluble factors released by Colon-26 was examined on growth of C2C12 myotubes in vitro in presence or absence of plum extract. Figure 8 (a,b) shows that in the absence of plum extract, soluble factors released in media derived from Colon-26 cells caused a significant reduction of C2C12 cell viability by ~25% (p<0.05). However, in the presence of plum extract, the negative effects of Colon-26-derived media on C2C12 viability was prevented and the cell viability was maintained to a similar level that was seen in the untreated cells.

Figure 8: The effect of plum extract on C2C12 viability in response to Colon-26-induced cytotoxicity. (a) Differentiated C2C12 myotubes were treated with normal medium or Colon-26-conditioned medium in the presence and absence of plum extract (50 μg/ml). (b) The viability of C2C12 myotubes were determined using WST-1 assay. The data is expressed as mean ± SD for at least 3 experiments. All comparisons were made to control (untreated cells) by one-way ANOVA and the significant differences are reported at *P<0.05.
4. Discussion

In our study we sought to investigate if plum had benefits on skeletal muscle. Specifically, we selected to use a plum extract that was enriched in polyphenols (~60% polyphenols) because the health benefits of plum have been partly attributed to its high polyphenol content [40-42]. Dried plum has previously been reported to have health benefits on bone. In rat models of osteoporosis, dried plum intake resulted in prevention and reversal of bone loss [43, 44]. A three-month clinical intervention study showed that dried plum intake improved biomarkers of bone formation in postmenopausal women, whereas longer term intake of dried plum resulted in mitigating loss of bone mineral density [30].

About 95% of total phenolic content in the plum extract used was present in the form of flavonoids. This data is not surprising as fruits are often reported to have phenolic compounds which are high in flavonoids with a range of 90-100% [45]. The anti-oxidant activity in the plum extract was found to be in range of 3-4 mM of Trolox equivalent/g, which is higher than that of turmeric (0.27 – 0.35 mM Trolox eq/g), and mulberry (1-2 mM Tolox eq/g) but lower than green tea (13-17 mM Trolox eq/g) and pomegranate (20-25 mMTrolox eq/g) [46-50]. Based on this high antioxidant activity, we decided to test the effect of plum extract on NFkB activation, since oxidative stress and inflammatory responses through activation of NFkB play an important part in muscle atrophy. Activation of NFkB plays a central role in muscle atrophy in several catabolic situations including cancer cachexia [51, 52]. We found that even a small dose of plum extract was able to almost completely inhibit (>80% inhibition) TNF-α-induced NFkB activity in vitro. It is likely that the proanthocyanidins, which comprise over 70% of the polyphenols, may be involved in suppressing the inflammatory cytokine (TNF)-induced activation of NFkB, although this has not been systematically tested with the individual components of the extract.

The present study was designed to analyze the effects of plum extract on muscle metabolism in C2C12 myotubules. In our initial experiments, effect of plum extract was tested on myoblast viability. The data show that this plum extract has no toxicity on the muscle cells, even at very high doses. These results are consistent with prior literature on plum effects on non-diseased cells [53]. Maintenance of muscle mass is dependent on synthesis of new proteins and breakdown of old or damaged proteins. If these processes are balanced, the muscle mass is maintained; however, with aging and under certain catabolic condition including cancer, renal failure or trauma, muscle protein degradation exceeds the synthesis of new proteins, and results in muscle atrophy [54]. One interesting observation was that both plum extract increased the size of growing myoblast under un-differentiated conditions, suggestive of inducing increase in cytoplasmic volumes by stimulating protein synthesis. We also measured effect of plum extract on protein synthesis and degradation in differentiated myotubules. Our data clearly demonstrated that plum extract not only increased protein synthesis but also inhibited myotubules protein degradation in response to serum starvation, demonstrating both anabolic and anti-catabolic effect.

The activity of the plum extract appears to be at least partly mediated through IGF-1 stimulation. Several studies have shown that IGFs stimulated both proliferation and differentiation of myoblasts, and plays a role in regenerating damaged skeletal muscle [55-58]. In line with our results, prior studies have also demonstrated that plums can increase IGF-1 levels in both humans [57] and animal models [60, 61]. One of the manifest of muscle loss is associated with decreased production of IGF-1 [62]. The signaling pathway IGF-1/PI3K/Akt (Insulin like growth factor -1/phosphatidylinositol 3-kinase/protein kinase) is considered the main mediator of normal muscle development and one of the most studied signaling molecular systems involved in muscle metabolism [63]. Akt activation leads to activation of mTOR (mammalian target of rapamycin), which is responsible for promoting protein synthesis. The Akt-mTOR signaling pathway and its downstream components (p70S6k and 4E-BPI) are attenuated with muscle wasting [64]. Further studies need to be performed to confirm if plum extract is indeed regulating Akt activity. The identification of compound or compounds in plum responsible for stimulating IGF-1 levels in myoblasts was beyond the scope of the present study. As discussed earlier, ursolic acid has been shown to increase muscle mass in mice exhibiting fasting-induced muscle atrophy [21] or
diet-induced obesity [22]. Interestingly, ursolic acid has also been shown to induce IGF-1 levels in
411 the skeletal muscle of these mice with an increased Akt phosphorylation [21, 22]. During present
412 investigation we were not able to detect ursolic acid in PE60 extracts due to technical limitation for
413 detecting all polyphenols; however, other studies have reported presence of ursolic acid in plums
414 [65]. It is, therefore, possible that ursolic acid to some extent may have contributed in IGF-1 mediated
415 muscle growth in our studies.
416 Cancer cachexia-related morbidity and mortality are often accompanied by whole body and
417 muscle loss [4, 7, 8], and it is suggested that blocking muscle wasting can prolong life despite tumor
418 growth [10]. The effect of plum extract on colon cancer cell viability, as well as its ability to protect
419 muscle cells from colon-cancer cell induced cytotoxicity, were, therefore, also investigated.
420 We used Colon-26 adenocarcinoma cells which is a widely used preclinical model because it
421 induces clinical cachexia, including its development as well as the resultant physiological and
422 metabolic impairment [39, 52, 66]. Treating the Colon-26 colon cancer cells with plum extract caused
423 a significant decrease in the Colon-26 cell’s viability, indicating potential anti-tumor activity.
424 It is known that muscle wasting in cancer patients is mediated through factors released from
425 tumor in circulation [67-70]. Studies have shown that elevated circulating levels of IL-6 mediated
426 skeletal muscle cell death in severely cachetic mice with colon cancer [71]. Our studies found that
427 plum extract can protect C2C12 myotubules from cytotoxicity induced by soluble factors released by
428 the Colon-26 cells. The exact pathways leading to reduced cell viability in response to tumor
429 induced soluble factors are not known, but it is possible that both atrophy and apoptosis may be
430 attenuated by the plum extract. It is also possible that compound(s) in plum extract may directly
431 effect colon cells to inhibit secretion of inflammatory cytokines. Future studies need to be conducted
432 to elucidate the molecular mechanism involved in the anti-cytotoxic activity of the plum extract.
433 Our current studies have several limitations. The study was performed using an in vitro system
434 that may not represent the complexities of an in vivo system. Furthermore, polyphenols in the plum
435 extract can undergo biotransformation in vivo which could either enhance or diminish the anabolic
436 effect of plum extract on muscle as well as its anti-inflammatory benefit. However, previous human
437 studies with dried plum still demonstrated its ability to activate IGF-1 as well as its
438 anti-inflammatory benefits, indicating that biotransformation may not result in loss of these effects
439 observed in our study.

5. Conclusions

In conclusion, the polyphenol-enriched plum extract has both anti-catabolic and anabolic effects
442 on muscle cells, as well as myogenic potential. In addition, this plum extract exhibited
443 anti-inflammatory activity as well as anti-cytotoxic properties in response to soluble factors released
444 from cancer cells. Thus, plum extract may be a useful intervention to be considered for cancer
445 cachexia or other chronic disease-induced cachexia involving inflammation. These results need to be
446 confirmed in an animal model of cachexia, followed by clinical translation.

Author Contributions: Conceptualization: RAS, and SLP; Experimentation and Data collection: FAS, HL,
450 PK, PJ; Manuscript writing: RAS, PJ, and SLP

Funding: The study was partly funded by a grant from Abbott-Nutrition, Columbus, OH, and by
452 Evans-Allen grant from USDA.

Acknowledgments: The financial support to Faten A. Alsolmei was provided by Saudi Arabian
454 Culture Mission, Kingdom of Saudi Arabia.

Conflicts of Interest: Drs. Suzette Pereira and Paul Johns are currently employed by Abbott.
456 Padmavathy Krishnan is an ex-Abbott employee. Drs. Rafat Siddiqui, Haiwen Li, and Ms. Faten
457 Alsolmei have no conflict of interest.
