**Abstract**

Optinalysis, as a method of symmetry detection, is a new advanced computational algorithm that intrametrically (within elements) or intermetrically (between elements) computes and compares two or more multivariate sequences in an unclustered or clustered manner as a mirror-like reflection of each other (optics-like manner), hence the name is driven. Optinalysis is based by the principles of reflection and moment about a symmetrical line which detects symmetry that reflects a similarity measurement. Optinalysis is suitable for quantitative and qualitative data types, with or without replications, provided it conform the algorithmic requirements there provided. Optinalysis can be organized for geometrical, geostatistical and statistical analysis in one-way, two-way, or three-way approach. A simulation comparisons shows that Optinalysis is a simple alternative approach of multivariate analysis of sociometric, demographic, socio-demographic, psychometric, ecological, experimental, genomic, nanoparticle and shape morphometric data. Optinalysis of these data matrix shows very similar results or conclusions with some multivariate analysis such as skewness measure, one-way ANOVA, paired t-test, one sample t-test, Tukey's multiple comparisons, BLAST sequence algorithmic analysis (percentages of identity, similarity, gabs, and positives, and the Needleman-Wunsch score), and Riemannian distance.

**Keywords:** Kabirian Coefficient; Symmetry; Similarity; Geometrical Analysis; Geostatistical Analysis; Statistical Analysis

## OPTINALYSIS

## Introduction

Lines and points as components of a geometric concept were established and invented by Mathematicians. Symmetry, on the other hand, is everywhere around us. Almost all living creatures such as plants, animals, and even humans are symmetric to a certain degree of geometry. Over time, we have imitated the symmetry of nature in art, architecture, technology and design. Symmetric shapes and patterns just seems to look more beautiful than asymmetric ones. But symmetry is more significant than simply looking beautiful. It lies at the very foundations of our universe, and to the greater impact, can even explain the most fundamental laws of physics (Fraassen, 1989; Mardia, et. al., 2000; Dryden and Mardia, 2016).

Natural and man-made structural entities and objects are everywhere, the information about these interesting structures and objects are routinely gathered and collected all around us, we appreciates the beauty of their nature, shapes, patterns and orientations. We recognize, identify, compare and distinguish amongst them by our innate senses. We often make rational decisions about these structural entities and objects base on their symmetry and structural orientations. Therefore, measure of symmetry is of great and global concern and for a wider interest in a variety of disciplines with theoretical concepts in mathematics and statistics; practical applications in biology, chemistry, medicine, image analysis, archaeology, bioinformatics, geology, particle science, genetics, geography, law, pharmacy and physiotherapy (Goodall, 1991; Bookstein, 1991; Dryden and Mardia, 1998; Cootes and Taylor 2010; Dryden, and Mardia, 2016; and Zheng *et. al.*, 2017).

In the literal texts, going from Weyl (1952); Darvas (2007), a widely accepted general definition of symmetry is not claimed coverable by a single mathematical definition and there is much to learn and to explore before stating whether or not a unique definition is possible. Even the practical definitions of symmetry are often based on strong assumptions and exemplified rather than defined (Petitjean, 2007). However, strong assumptions, such as the existence of the euclidean structure for geometric symmetries, Riemannian distance, Minkowski distance, Mahalanobis distance, simple matching and Jaccard coefficient are some measures of similarity.

Similar and symmetrical entities are invariance to transformational properties such as reflection, rotation, scaling, and translation. The decisions we made about this invariance under different transformations are based on strong assumption with no general formula to explain. Petitjean (2007) associated the topic of symmetry with the classification of symmetries, which should be done on the basis of the symmetry group structure of the object and symmetry is considered as a quantity varying continuously.

In this paper, a new algorithm called Optinalysis, is proposed and explained. Optinalysis torches the most important aspects of geometrical analysis, statistical analysis, and also a new derived concept of geostatistical analysis. Optinalysis does not require the assumption of normality and other statistical or geometric features, but it requires the existence or establishment of a clearly defined sequence order within and/or between the elements of a multivariate sequences. Several examples were examined and analyzed, and in comparison with other standard methods of statistical and geometrical analysis, revealed that Optinalysis presented a uniquely new paradigm of data analysis.

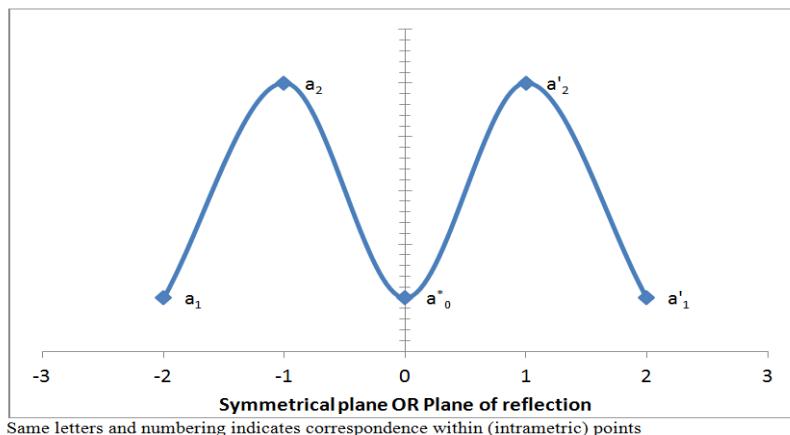

## OPTINALYSIS

## 1.0 The Algorithm of Optinalysis

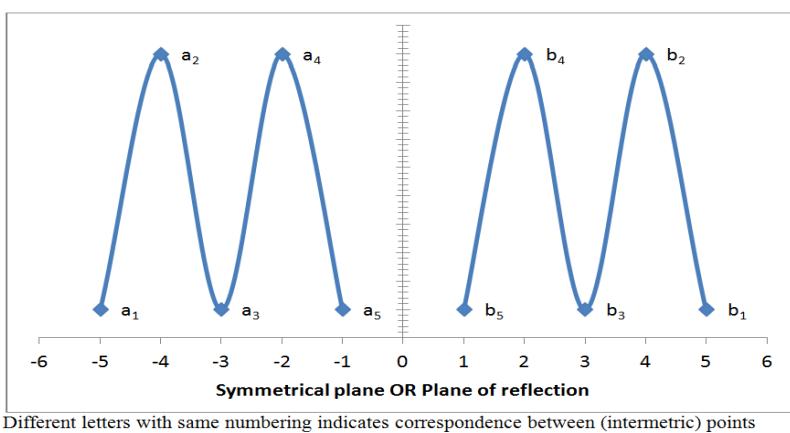

The paradigm of the concept of symmetry is the mirror image. My image and I are a symmetric pair to each other by their corresponding points that matches within and between them. Other kinds of symmetry exist, but this is the one to start with. It is called *isosymmetry*.

To make this illustrative and precise, consider the case of one *M* letter (Figure 1) in a plane. Elements of letter *M* ( $a_n$  and  $a'_n$ ) may be related as follows: there is a straight line that separates these elements (*the line of reflection*) and each point ( $a_n$ ) within *M* can be connected to a corresponding point ( $a'_n$ ) within *M* by means of a line perpendicular to lower base of the letter *M*. The correspondence connects all points ( $a_n$  and  $a'_n$ ) in *M* such that corresponding points are equidistant from the line of reflection.

In another illustrative case of two *M* letters (Figure 2) in a plane. Letter  $M_1$  and  $M_2$  may be related as follows: there is a straight line that separates them (*the line of reflection*) and each point ( $a_n$ ) in  $M_1$  can be connected to a corresponding point ( $b_n$ ) in  $M_2$  by means of a line perpendicular to lower base of the letter *M*. The correspondence connects all points ( $a_n$  and  $b_n$ ) in  $M_1$  and  $M_2$  and is such that corresponding points are equidistant from the line of reflection. In space, the definition is similar, but with a *plane of reflection*. Scholarly works such as Weyl (1952), Darvas (2007), Kendall (1989), Watson (1986), Bookstein 1986, 1991; Kent (1994), Lele and Richtsmeier (2001) and Dryden *et. al.* (2008) follows same line with this principle.

**Figure 1:** Showing a symmetric correspondence within pair points of letter *M*.

**Figure 2:** Showing a symmetric correspondence between pair points of two *M* letters.

## OPTINALYSIS

The Algorithm of Optinalysis is within this tradition and concept of symmetry. Optinalysis attempted to detect symmetry within and/or between the corresponding points of pair of structural elements of sequences. Optinalysis is however designed to intrametrically or intermetrically compare two or more multivariate sequences in an unclustered or clustered manner as a mirror-like reflection of each other (optics-like manner).

### 1.1 Step-by-step Computational Approach to Optinalysis

**Step 1:** Identify the variables and elements (which can be an experimental observations; frequencies; measurements from interval, ratio, ordinal, or nominal scales; coordinates of landmarks; vector coordinates, or resultant functions to be analyze).

**Step 2:** If the data set is in nominal form, an appropriate transformation method (e.g, Kabirian (A) or Kabirian (B) algorithmic transformation) must be used to convert the data sequence into a logical and numerical scores. Section 3 presented detail explanations of the algorithm.

**Step 3:** Identify, establish and organize a logical sequence (sequence order) and arguments within and between the elements of the subject or query sequence(s) of variable(s) and as a well as the reflector sequence of variable(s). Section 5 presented detail explanations on methods of establishing sequence order. If landmark coordinates are involved, then, the sequencing within and between the selected landmarks is organized by the appropriate numbering methods used as described in section 7 of this paper. The choice of sequence order depends on the type of Optinalysis intend to detect (i.e: geometric, geostatistical, or statistical).

**Step 4:** If the main elements of the comparing sequences are associated with other co-elements (e.g, landmark coordinates into  $x, y, z$  points), then, a suitable functions (e.g, geometrical functions, vectors resolution, or any applicable theoretical function) must be used to obtain the resultant elements. Section 14 presented detail explanations.

**Step 5:** Choose the desired rotation and/or normalization value, if in case the rotation and normalization effects are considered important. Section 12 and 20 respectively presented detail explanations on rotations and normalization of a given sequences.

**Step 6:** Establish a pairwise reflecting correspondence or alignment within and between the query and the reflector sequences. Section 8 presented detail explanations on the different pairing styles.

**Step 7:** Quantitatively scale the resultant sequence elements as they were reflectively paired or aligned. Section 13 and Table 9-10 presented detail explanations.

**Step 8:** Compute for the Kabirian coefficient of symmetry (similarity), the probabilities, or percentages. Section 14 presented detail description of the formula for these parameters.

## 2.0 What data sequence can be compared by Optinalysis

Data sequences from quantitative and qualitative measurements are welcome for Optinalysis.

### 2.1 Quantitative Data

Quantities can be scalar or vectors. For scalar quantities, it is very suitable for statistical Optinalysis. But for geometrical and geostatistical Optinalysis, a clearly defined sequence order within or/and between variables and as well as the elements must be established. On other hand, vector quantities are expressed by their coordinates (in magnitude and direction) in 2-D structure ( $x, y$ ) or in 3-D structures( $x, y, z$ ). For such a vector data to suit Optinalysis, the coordinates (i.e, the elements) need to be resolved.

## OPTINALYSIS

In the case of nominal data (e.g, the nucleotide base sequences of DNA, or the amino acid sequences of protein, or words strings, etc), a suitable algorithms (e.g, Kabirian A and B transformation methods) is neccesary to transform these nominal data to a logically numerical sequences.

### 2.2 Qualitative Data

Qualities such as response rating or ranking scores, colors, and other forms of descriptions, can be compared by Optinalysis provided there have a clearly defined sequence order within or/and between them. The sequence order can be a theoretically established or based on the rating or ranking scale used.

## 3.0 Kabirian (A) Algorithmic Transformation

This involved the use of binomial codes to convert nominal data sequence of variables or attributs, in an unclustered or clustered form, into a logical and numerical sequence based on Kabirian (A) algorithmic score. In this algorithmic approach, 0, 1, -1 are used to express reflective or corresponding pairwise matching, mismatching and gaping between two contracting attributes or variables. Two methods works with this algorithm. These are:

### 3.1 Unclustering

It is a plain matching, mismatching and gaping reflective correspondence between the aggregate elements of the two pairwise sequences. In this case, each sequence element is compared to its corresponding pair to assign a score that express their matchness, mismatchness and gapness. Reflective Unclustered Match-mismatch-gab Approach (RUMMG-(io)A) is used to describe this technique (Table 2). It aim to inegrate a measure of how much of the sequence elements matched, mismatched, and gabbed with respect to an organized unclustered sequence order. Table 2 Provided an illustration of how the algorithm works.

**Table 1:** Algorithm of Reflective Unclustered Match-mismatch-gab Appraoach

Pairewise	Example		Scoring			Optinalysis
	Query Seq.	Reflector Seq	Query Seq.	Reflector Seq	Optinalysis	
Match	A	A	1	1	1.00 (100%)	
Mismatch	A	G	1	0	2.00 (0%)	
Abberative gab	A	-	1	-1	0 (-100%)	
Abberative gab	-	A	-1	1	0 (-100%)	
Abberative gab	-	-	-1	-1	1.00 (100%)	
Non-abberative gab	#	#	0	0	1.00 ( $\pm$ 100%)	

### 3.2 Clustering

Refers to the associating two or more sequence elements into a one meaningful unit, or cluster, or group. Asteric sign (\*) is used to separate between clusters. Within each cluster in consideration, a single or combination of more than one attributes (these attributes are: match, mismatch, or gap) can be observed. Those clusters with only one, only two, and only three attributes are called *unimorphic*, *dimorphic* (*bimorphic*), and *trimorphic clusters* respectively. The dimorphic and trimorphic clusters form the *polymorphic clusters*. A polymorphic clusters are judge or ruled during Kabiran algorithmic transformation by reflective clustered match-mismatch-gab appraoach using two resolution types.

**Type I Resolution Rule:** Where match, mismatch, and gab exist in a give cluster relative to its pairewise, the resultant score for that particular cluster should be resolved by gab rule; if not gab, then by mismatch rule; if none of these two events, then is a match and by match rule.

## OPTINALYSIS

**Type II Resolution Rule:** Where match, mismatch, and gab exist in a give cluster relative to its pairwise, the resultant score for that particular cluster should be resolved by mismatch rule; if mismatch, then by gab rule; if none of these two events, then is a match and by match rule.

Reflective Cluster Match-mismatch-gab-(io) Approach (RCMMG-(io)) is used to describe this technique (Table 2). It aim to inegrate a measure of how much of the sequence elements matched, mismatched, and gabbed with respect to an organized clustered sequence order. In an alternative consideration, Reflective Cluster Match-mismatch-gab-(nio) Approach (RCMMG-(nio)) can be used (Table 3). It also aim to inegrate a measure of how much of the sequence elements matched, mismatched, and gabbed without respect to an organized cluster sequence order. Table 3 provided an illustrative examples.

**Table 2:** Algorithm of Reflective Cluster Match-mismatch-gab-(io) Approach

Pairewise	Example		Scoring		
	Query Seq.	Reflector Seq.	Query Seq.	Reflector Seq.	Optinalysis

Abberative gab	*ATC*	*AT -/*AC -/*TC -*			
Non-abberative gab	/###/	/###/	0	0	1.00 (±100%)

#### 4.0 Kabirian (B) Algorithmic Transformation

This method involve counting the frequency of matched, or mismatched or gapped elements of a clustered sequences as it is compared in pairwise manner. Seven techniques works with this algorithm. These are:

- Reflective Cluster Match-(io) Frequency Approach (RCM-(io)FA): Estimates how much of the sequence elements are conserved with respect to an organized cluster sequence order. Illustrative examples are in Table 4.
- Reflective Cluster Match-(nio) Frequency Approach (RCM-(nio)FA): Estimates how much of the sequence elements are conserved without respect to an organized cluster sequence order. Illustrative examples are in Table 5.

## OPTINALYSIS

- iii. Reflective Cluster Mismatch-(io) Frequency Approach (RCMm-(io)FA): Estimates how much of the sequence elements are abberated or abnormal by inversion or translocation with respect to an organized cluster sequence order. Illustrative examples are in Table 4.
- iv. Reflective Cluster Mismatch-(nio) Frequency Approach (RCMm-(nio)FA) Estimates how much of the sequence elements are abberated or abnormal by inversion or translocation without respect to an organized sequence order. Illustrative examples are in Table 5.
- v. Reflective Cluster Gab-(io) Frequency Approach (RCG-(io)FA): Estimates how much of the sequence elements are abberated or abnormal by deletion or omission, addition or duplication with respect to an organized cluster sequence order. Illustrative examples are in Table 4.
- vi. Reflective Cluster Gab-(nio) Frequency Approach (RCG-(nio)FA): Estimates how much of the sequence elements are abberated or abnormal by deletion or omission without respect to an organized cluster sequence order. Illustrative examples are in Table 5.
- vii. Standard Score Approach (SSA): Estimates how much of the sequence elements are similar or equivalent by a given standard scores. Illustrative examples are in Table 6.

**Note** that, other methods of identity search considered the whole sequence as a cluster not in order, to genetate match, mismatch and gab scores. This modalities and rule distinguishes these approach overs the other well-known and adopted methods. The former works when the sequences are aligned and the later ignore sequence alignment. For each pairwise elements, a score is assigned using the rules in Table 4 and 5.

**Table 4:** Algorithm of Reflective Cluster Match-(io), Mismatch-(io), Gab-(io) Frequency Appraoach

Pairwise	Example		Scoring	
	Query Seq.	Reflector Seq.	Query Seq.	Reflector Seq.
Match-(io)	*ATC*	*ATC/*ACT/*TCA/*CTA/*AGC/*GTC/*AAT*/ * - - */- TC/*A - C/*AT -*/..etc	3	3/1/0/1/2/1/0/2/2

**Table 5:** Molecular Mass Score Approach

DNA Bases and Gabs	Molecular Mass Score Approach	Remarks
Adenine (A)	≈ 135 g/mol	
Tymine (T)	≈ 126 g/mol	
Cytosine (C)	≈ 111 g/mol	
Guanine (G)	≈ 151 g/mol	
Uracil (U)	≈ 112 g/mol	
All other Gabs	0	

Note: Ranking is based on molecular mass of the nitrogen bases.

**4.1 Unification**

During Kabirian (B) algorithmic transformation, clusters may have unequal number of elements, called *ambiguous clusters* (Seen Table 7 and its application in word semantics in section 22.6). These ambiguous clusters result to an ambiguous and unjustified results. To solve this transformation barrier, a technique called **Unification** is introduced to resolve only those ambiguous clusters by deliberate addition of a neutral effect to the similarity (match) attribute. Non-abberative gaps, symbolized by ‘ # ‘ is used pairwisely in each of the affected and ambiguous clusters.

**Table 7:** Unification of ambiguous clusters

Example	Sequence	No. of elements in each cluster	Remarks
Sequence I	Psy*cho*lo*gy	3*3*2*2	Unequal clusters setting
Sequence II	Bio*in*for*ma*tics	3*2*3*2*4	Unequal clusters setting
Sequence I	Psy*cho*lo##*gy#	3*3*3*3	Unified clusters
Sequence II	Bio##*in##*for##*ma##*tics	4*4*4*4*4	Unified clusters

**5.0 Selecting an Appropriate Sequence Order for the Data Set****5.1 Theoretical Order**

The order is based on the geometrical orientations, or theoretical explanations or natural phenomena. For instance, nucleotide base and amino acid sequences, systematic numbering of shape landmark coordinates, socio-demographic hierarchies established by Abdullahi (2019b), chemical concentrations, rating and ranking response descriptors are some examples. In this

## OPTINALYSIS

case, the position and pattern orientation of each element of the attribute is preserve and kept in its natural order. This is important for geometrical and geostatistical Optinalysis.

### 5.2 Ascending/descending Order

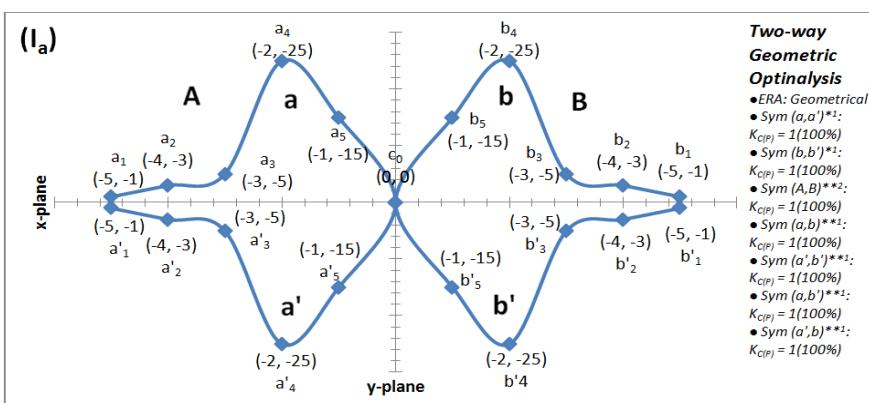

The position and pattern orientation of all elements or group of elements of the sequence is reorganized in ascending or descending order. It disregards the inherent sequence of the data set. This is important for geostatistical and statistical Optinalysis.

**5.2.1 Ascend/descend within:** the reorganization is within each group or data set (replicates or repeated measurements) of elements of the comparing sequences, but the inherent order between the variables are conserved. Thus, it only disregards the inherent sequence within the data set. This is mainly important for geometrical and geostatistical Optinalysis that involved replications or repeated measurements of observation. It is called type (I) geometrical or geostatistical Optinalysis if ascending order is chosen, while it is called type (II) geometrical or geostatistical Optinalysis if descending order is used.

**5.2.2 Ascend/descend between:** the reorganization is within and between all the elements of the comparing sequences, with or without a replications or repeated measurements. It disregards the inherent sequence within and between the data set. This is important for statistical Optinalysis. It is called type (I) statistical Optinalysis if ascending order is chosen, while it is called type (II) statistical Optinalysis if descending order is used.

## 6.0 Acquiring the Symmetry Groups (Landmarks) Based on Geometrical Scale.

For a any data to fit the requirements for Geometrical and Geostatistical Optinalysis, the landmarks has to be in a geometrical scale (the scale invariant format). A geometrical scale is uniform point measurement (without variation due to graphic scaling effect) from the left to right, from the upper to lower points of the selected landmarks about a symmetrical line/plane. Two (2) types of geometrical scaling, namely positive and negative geometrical scaling, were indentified to be fit for geometric Optinalysis. A uniform geometric scaling can be acquired on any geometrical coordinate graphs such as Bookstein and Procrustes landmark coordinates if the axes are scale edited to a uniform vector. Note that, any edited axis can bear either a positive or a negative integer. Figures 3-8 are the graphical illustration of each geometrical scale type.

## 7.0 Numbering of Symmetry Groups (Landmarks)

The choice of appropriate numbering style is crucial way of designing how elements of the data set pairewisedly corresponds and reflects. The numbering style also guide what plane (axis) of symmetry are the elements reflects. Here are some styles of landmark numbering.

### 7.1 Methods of Landmark Numbering and Reflection about an Axis

Where geometrical and geostatistical symmetry detection involves the use of symmetry groups/points/landmarks, a systematic numbering style is essential for the establishment of a clear sequence structure and a distinct 'head' and 'tail'. A clearly defined 'head' and 'tail' points allow for appropriate sequence pairing. And a clearly defined systematic numbering tells what planes are the sequences elements are designed to reflect about and also associate the functional relationship within and between the main elements and the co-elements. Vertical and horizontal numberings all express symmetry about x-plane, y-plane and z-plane, and are suitable for intrametric and intermetric symmetry detection by geometric Optinalysis. While the cyclic numbering express symmetry about z-plane and are more suitable for intermetric geometric

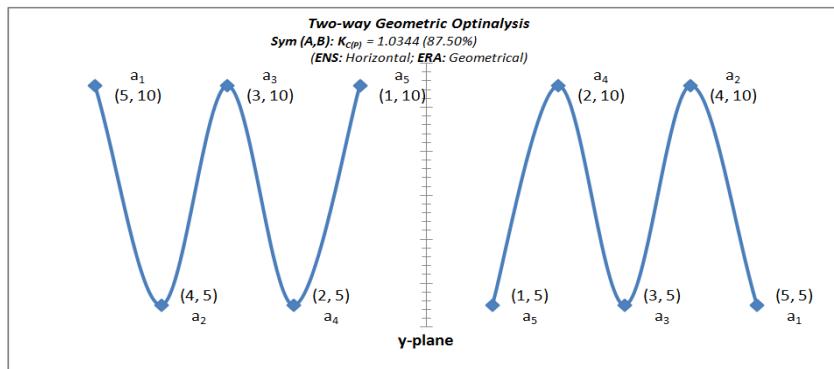

## OPTINALYSIS

Optinalysis. Three (3) different numbering styles were identified and demonstrated in Figures 9-13.

**7.1.1 Horizontal numbering:** In this style, the numbering of elements starts from the left to the right, or from the right to the left. Where two or more elements lies tangent to the moving direction, those elements most away the symmetrical plane are prioritized over those most closer to the symmetrical plane in consideration. Figure 9 provided examples of horizontal numbering for intermetric Optinalysis.

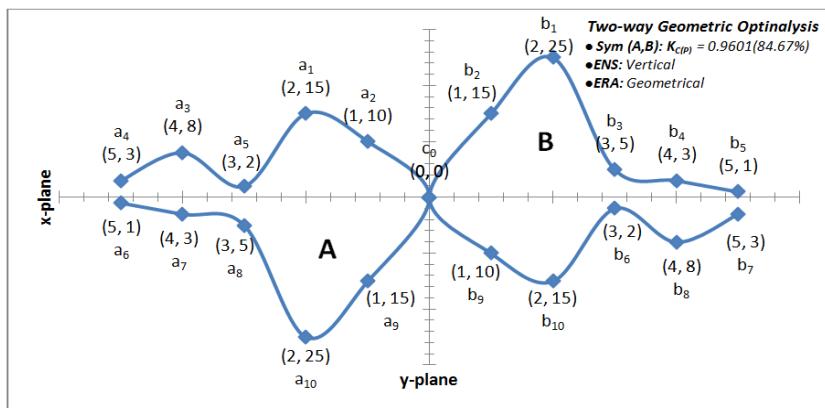

**7.1.2 Vertical numbering:** In this style, the numbering of elements starts from the upper to the lower or from the lower to the upper once. Where two or more elements lies tangent to the moving direction, those elements most away the symmetrical plane are prioritized over those most closer to the symmetrical plane in consideration. Figures 10 and 11 provided examples of vertical numbering example for intermetric Optinalysis

**7.1.3 Cyclic numbering:** In this style, the numbering of elements starts from any point/side (e.g, left, right, upper, or lower) and moving in clockwise or anti-clockwise direction. Where two or more elements lies tangent to the moving direction, those elements most away the symmetrical plane are prioritized over those most closer to the symmetrical plane in consideration. Figures 12 and 13 provided examples of cyclic numbering for intermetric Optinalysis.

**Figure 13:** Shows an intermetric symmetry between A and B structures about z-plane. The numbering style is cyclic, moving in clockwise and in the other hand anti-clockwise directions about an x-plane.

## OPTINALYSIS

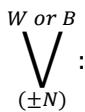

### 8.0 Pairing Styles

Pairing style tells us how the sequences of two intermetric elements pairewisesly reflect. A pairwised sequences symmetry can be detected on different pairing style. The choice of appropriate pairing style depends on the consideration made on where (i.e, beginning or end of the sequence elements) should be more sensitive to any imbalances/changes or otherwise. Pericentral rotation and numbering style can help achieve a desired sequence pairing. Here are the styles in symmetry detection.

**8.1 Head-to-head Pairing (H-H):** one ends of the two pairing sequences called the head (the start point) are both allowed to be on the most sensitive node. Pericentral E-rotation can help achieve this sequence pairing.

**8.2 Tail-to-tail Pairing (T-T):** one ends of the two pairing sequences called the tail (the end point) are both allowed to be on the most sensitive node. Pericentral E-rotation can help achieve this sequence pairing.

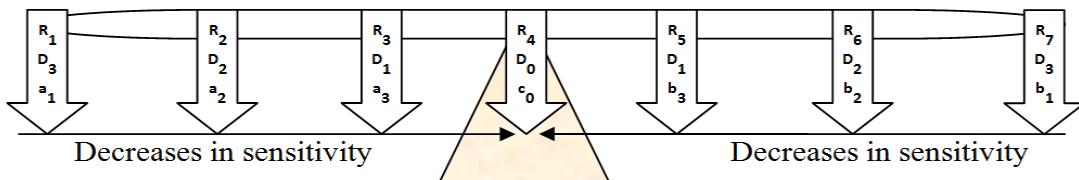

**8.3 Head-to-tail Pairing (H-T) or Tail-to-head Pairing (T-H):** one of the ends of the two pairing sequences called the head or tail (the start or end point) is allowed to be on the most sensitive node and other on the less sensitive node. Pericentral S-rotation can help achieve this sequence pairing.

### 9.0 Sensitivity points

Sensitivity point is any node that when considered a variable can exert a certain degree of imbalances in the distribution of elements (variables) about a dividing line or plane. Each node has its own unique characteristic sensitivity which increases away from the central node and decreases towards the central node(s). Sensitivity of a point generally decreased with increase in sequence elements. Figure 14 is an illustrative example.

The nodes with components  $R_1, D_3, a_1$  and  $R_7, D_3, b_1$  are the most sensitive points of the upper and lower stems respectively. The node with components  $R_4D_0C_1$  is the central node.

Note:  $R_n$  = Quantitative scale;  $D_n$  = Displacements;  $a_n$  and  $b_n$  are paired variables/elements;  $c_n$  = Central variable

**Figure 14:** Sensitivity points of sequence elements.

### 10.0 Reflection and Moments

All symmetrical structures reflect momentarily (i.e, in same moment or in same total moments) about a symmetrical plane/point. Reflection can be: (1) Normal reflection, characterized by a plane mirror reflection, equidistance reflection from the central node, (2) Rescaled reflection, characterized by the reduction in magnitude and increase in displacement or

## OPTINALYSIS

increase in magnitude and reduction in displacement. Normal reflection is what produces eu-symmetric structures, while re-scaled reflection is what produces pseudo-symmetric structures. Eu-symmetrical entities reflects equidistance from the central node, plane mirror image of each other, the subject and the reflector sequences have the same moments about the symmetrical plane/axis, and geometrically and geostatistically stable to E-rotation. While pseudo-symmetrical entities do not reflects equidistance from the central node, spherical mirror image of each other, the subject and the reflector sequences also have the same moments about the symmetrical plane/axis, and are geometrically and geostatistically instable to E-rotation.

Reflection and moments are two companion mechanisms upon which the principle of Optinalysis operates.

If the query moment is equal to the reflector moment, then two comparing entities are geometrically, geostatistically and statistically symmetrical intrametrically.

$$a_n \times D_n = a'_n \times D_n$$

And/or if the total query moments is equal to the total reflector moments, then two comparing entities are geometrically, geostatistically and statistically symmetrical intrametrically.

$$\sum(a_n \times D_n) = \sum(a'_n \times D_n)$$

If the query moment is equal to the reflector moment, then two comparing entities are geometrically, geostatistically and statistically symmetrical intermetrically.

$$a_n \times D_n = b_n \times D_n$$

And/or the total query moments is equal to the total reflector moments, then two comparing entities are geometrically, geostatistically and statistically symmetrical intermetrically.

$$\sum(a_n \times D_n) = \sum(b_n \times D_n)$$

Suppose we refer to Figure 3, we find that intrametrically (within the sequence elements),  
 $a_1$  is normally reflected momentarily about x-plane as  $a'_1$   
 $a_2$  is normally reflected momentarily about x-plane as  $a'_2$   
 $a_3$  is normally reflected momentarily about x-plane as  $a'_3$   
 $a_4$  is normally reflected momentarily about x-plane as  $a'_4$   
 $a_5$  is normally reflected momentarily about x-plane as  $a'_5$   
 $b_1$  is normally reflected momentarily about x-plane as  $b'_1$   
 $b_2$  is normally reflected momentarily about x-plane as  $b'_2$   
 $b_3$  is normally reflected momentarily about x-plane as  $b'_3$   
 $b_4$  is normally reflected momentarily about x-plane as  $b'_4$   
 $b_5$  is normally reflected momentarily about x-plane as  $b'_5$

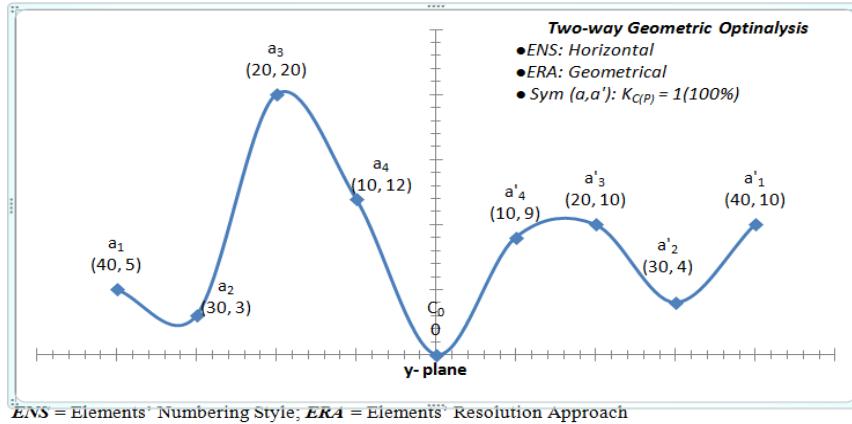

And also intermetrically (between the sequence elements),

$a_1$  is normally reflected momentarily about y-plane as  $b_1$   
 $a_2$  is normally reflected momentarily about y-plane as  $b_2$   
 $a_3$  is normally reflected momentarily about y-plane as  $b_3$   
 $a_4$  is normally reflected momentarily about y-plane as  $b_4$   
 $a_5$  is normally reflected momentarily about y-plane as  $b_5$   
 $a'_1$  is normally reflected momentarily about y-plane as  $b'_1$   
 $a'_2$  is normally reflected momentarily about y-plane as  $b'_2$   
 $a'_3$  is normally reflected momentarily about y-plane as  $b'_3$   
 $a'_4$  is normally reflected momentarily about y-plane as  $b'_4$   
 $a'_5$  is normally reflected momentarily about y-plane as  $b'_5$

In another case in Figure 15, we can find that intrametrically (within the sequence elements),

## OPTINALYSIS

- $a_1$  is spherically reflected momentarily about y-plane as  $a'_3$
- $a_2$  is spherically reflected momentarily about y-plane as  $a'_4$
- $a_3$  is spherically reflected momentarily about y-plane as  $a'_1$
- $a_4$  is spherically reflected momentarily about y-plane as  $a'_2$

**Figure 15:** A pseudo-symmetrical distribution with a spherically reflected elements

### 11.0 Planes/Axis of Symmetry and Reflection

Elements of sequences can be reflective momentarily on x, y, and z planes. Mono-axial, bi-axial and tri-axial symmetry. On the basis of the number of planes a sequences elements can be symmetrically quantified, three types of symmetry are recognized.

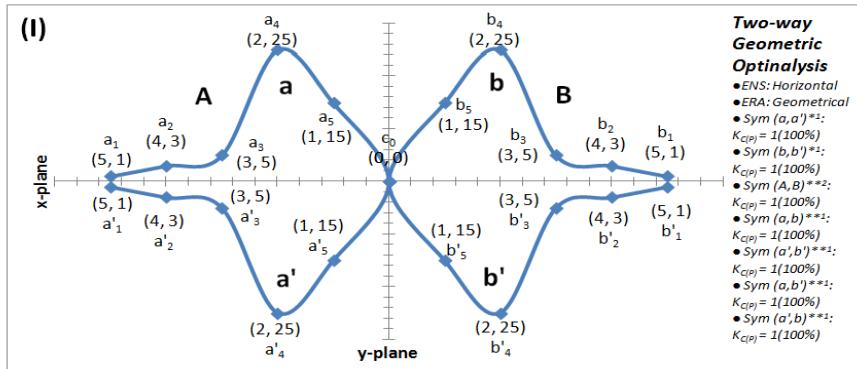

- I. Mono-axial or mono-planal symmetry: An entity or structure is said to be mono-axial when it can only be quantified on one plane of symmetry. This symmetry characterizes bi-lateral objects.
- II. Bi-axial or bi-planal symmetry: An entity or structure is said to be bi-axial when it can be quantified on two planes of symmetry. This symmetry characterizes radially symmetrical objects.
- III. Tri-axial or tri-planal symmetry: An entity or structure is said to be tri-axial when it can be quantified on all the three planes of symmetry. This symmetry confirms the characterization of radially symmetrical objects.

### 12.0 Rotation and stability (Rotational invariance)

Rotational stability described the geometrically and geostatistically symmetric stability of a pattern or distribution of elements as the elements rotates  $180^0$  around the central node (called the central or C-rotation) or the pericentral node (called the pericentral rotations).

Suppose we have a geometrical distribution in Figure 16, we shall see how it changes as a result of different kind of rotations about a symmetrical plane.

 \*\*Symmetry of different lettered correspondence expresses intermetric symmetry  
<sup>1</sup>Horizontal numbering style  
<sup>2</sup>Vertical numbering style

**Figure 16:** A symmetrical distribution of intermetric distribution

**12.1 Central rotation:** (called the C-rotation) refers to the rotation of the sequence elements around the central node of that distribution. Central rotation is a character that checks and proves the rotational equivalence of a distribution on a quantitative scale. Hence, the central rotation gives different Kabirian coefficients of similarity representing the same significance probability level. Central C-rotation (rotation through 180°) turns the patterns of the distribution in figure 16 to a pattern in figure 17.

 \*\*Symmetry of different lettered correspondence expresses intermetric symmetry  
<sup>1</sup>Horizontal numbering style  
<sup>2</sup>Vertical numbering style

**Figure 17:** C-rotation about y-plane of intermetrically and radially symmetrical distributions.

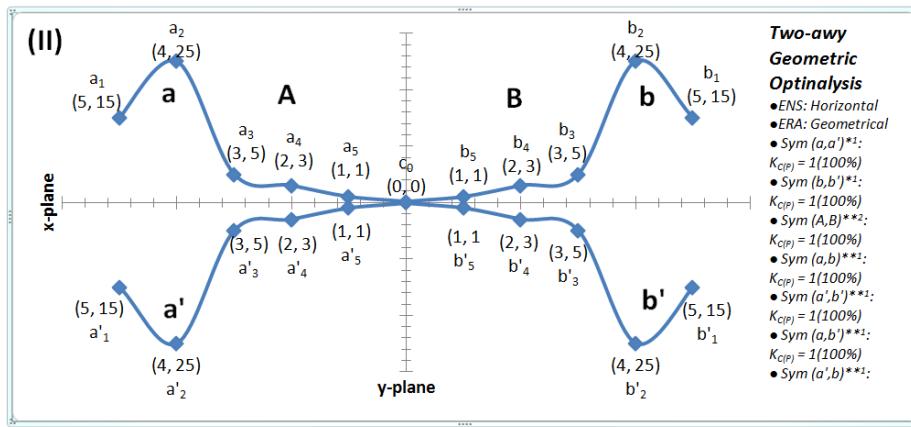

**12.2 Pericentral rotation:** refers to the rotation of geometrical or geostatistical elements around the pericentres of that distribution.

### Patterns of pericentral rotation

**12.2.1 Pericentral E-rotation:** refers to the rotation of elements around the pericentre of a given distribution. It is the test of symmetric stability or instability of a given geometrical or geostatistical distribution of sequence elements about a symmetric plane. Following pericentral E-rotation, head-to-head pairing turns into a tail-to-tail pairing and reverse is the case. Pericentral E-rotation is used to check the geometrically symmetric behavior of a given distribution. Elements of intrametric or intermetric distributions can be symmetrically stable or instable to

## OPTINALYSIS

pericentral E-rotation. Maintaining a geometrically symmetric stability following E-rotation is exclusive to eu-symmetric distribution. While geometrically symmetric instability (lost or gain in symmetry) following pericentral E-rotation is exclusive to pseudo-symmetric distribution. Pericentral E-rotation (rotation through  $180^0$ ) turns the patterns of the distribution in figure 16 to a pattern in figure 18.

\*\*Symmetry of different lettered correspondence expresses intermetric symmetry

<sup>1</sup>Horizontal numbering style

<sup>2</sup>Vertical numbering style

**Figure 18:** Pericentral E-rotation about y-plane of intermetrically and radially symmetrical distributions.

**12.2.2 Percental S-rotation:** refers to the rotation of elements around the pericentre of that distribution. The S-rotation produces head-to-tail or tail-to-head pairing. If elements of a geometrically symmetric distribution S-rotates, it is more likely (except polyaxially or radially symmetric structures) to losses its geometric symmetry. Pericentral S-rotation (rotation through  $180^0$ ) turns the pattern of the distribution in Figure 16 and 21 to a pattern in Figure 17-18 and 20-21 respectively. In some cases, geometrically asymmetric pattern, following S-rotation may gain a geometrical symmetry about a certain symmetry plane (Figure 22-23).

## 13.0 Quantitative scale

Denoted by ' $r_n$ ' are numbers arbitrarily assigned to rank every point, called the node, of a sequence in a very logical manner in such a way that every node has its own unique characteristic sensitivity to a changing magnitude. Note that, quantitative scale is different with geometric scale. The symmetric status of a given sequence remains invariant under any quantitative scaling provided a uniform difference (common difference) is maintained between each scale point to its proceeding point.

## 14.0 Computations/Calculations

To begin describing how the symmetry detection formulae were driven, we need to be familiar with these used terms.

**Elements:** Denoted by ' $p_n$ ' are main components of a set of sequence.

**Co-elements:** Denoted by ' $d_n$ ', ' $e_n$ ' are any supporting and accompanying element(s) represented both in magnitude and/or direction that dependently or proportionately determine or change the function of the main element of a set of a sequence. For instance, in geometry, any of the  $x, y, z$  coordinates can be a main element, and the others as co-elements.

**Resultant Elements:** Denoted by ' $a_n$ ', ' $a'_n$ ', ' $b_n$ ', and ' $b'_n$ ' are the outcomes of an established function which can summarize, harmonize and integrate the main element with its associated co-elements into a single value. Resultant elements are essential for two-way or three-away Optinalysis which can be achieved by several standard functions appropriate to the subject matter. Such standard functions include geometrical functions (e.g area, volume, centroid size), vector functions (e.g resultant magnitude), mathematical functions (e.g cumulative score of an observation and its frequency), or a theoretical functions (e.g a product relationship between a specific value score and its relative population activists). These resolutions of elements are referred to as elements resolution approaches (ERA). Table 8 expresses some examples of functional resolution of elements of a symmetry group.

## OPTINALYSIS

**Table 8:** Elements, co-elements and their resultant functional interactions.

Element ( $d_n$ )	Co-element 1 ( $d_n$ )	Co-element 2 ( $e_n$ )	Resultant Magnitude By Geometrical Approach $a_n = (p_n \times \Delta d_n \times \Delta e_n)$	Resultant Magnitude By Vector Approach $a_n = \sqrt{p_n^2 + d_n^2 + e_n^2}$
$p_1$	$d_1$	$e_1$	$a_1 = (p_1 \times \Delta d_1 \times \Delta e_1)$	$a_1 = \sqrt{p_1^2 + d_1^2 + e_1^2}$
$p_2$	$d_2$	$e_2$	$a_2 = (p_2 \times \Delta d_2 \times \Delta e_1)$	$a_2 = \sqrt{p_2^2 + d_2^2 + e_2^2}$

$p_0^*$	$d_0^*$	$e_0^*$	$a_0^* \text{ or } c_0 = (p_0^* \times \Delta d_0^* \times \Delta e_0^*)$	$a_0^* \text{ or } b_0 = \sqrt{p_0^{*2} + d_0^{*2} + e_0^{*2}}$
$p'_5$	$d'_5$	$e'_5$	$a'_5 \text{ or } b_5 = (p_5 \times \Delta d'_5 \times \Delta e'_1)$	$a'_5 \text{ or } b_5 = \sqrt{p'_5^2 + d'_5^2 + e'_5^2}$
$p'_4$	$d'_4$	$e'_4$	$a'_4 \text{ or } b_4 = (p_4 \times \Delta d'_4 \times \Delta e'_1)$	$a'_4 \text{ or } b_4 = \sqrt{p'_4^2 + d'_4^2 + e'_4^2}$
$p'_3$	$d'_3$	$e'_3$	$a'_3 \text{ or } b_3 = (p_3 \times \Delta d'_3 \times \Delta e'_1)$	$a'_3 \text{ or } b_3 = \sqrt{p'_3^2 + d'_3^2 + e'_3^2}$
$p'_2$	$d'_2$	$e'_2$	$a'_2 \text{ or } b_2 = (p_2 \times \Delta d'_2 \times \Delta e'_1)$	$a'_2 \text{ or } b_2 = \sqrt{p'_2^2 + d'_2^2 + e'_2^2}$
$p'_1$	$d'_1$	$e'_1$	$a'_1 \text{ or } b_1 = (p_1 \times \Delta d'_1 \times \Delta e'_1)$	$a'_1 \text{ or } b_1 = \sqrt{p'_1^2 + d'_1^2 + e'_1^2}$

**Sclements:** Denoted by ' $S_m$ ' it is expressed as the product of elements, co-element(s) and its bearing quantitative scale.

**Node:** Denoted by ' $n$ '. A node comprised of any specific quantitative scale's units, its bearing element and co-elements.

**Query and Reflector Nodes/Query and Reflector Sequences:** Query and reflector nodes describe respectively the nodes on which the elements of a query and reflector sequences are organized. Reversely, Query and reflector sequences describe respectively the sequence on which the components of a query and reflector nodes are organized. A query and reflector node may be mononodal (comprising of only one node, specifically with a univariate sequence) or polynodal (comprising of more than one node, specifically with a multivariate sequence).

**Pericentral Node:** Denoted by ' $PC_n$ '. It describes one of the query or reflector nodes that divide each of the components (the query and the reflector sequence) into two equal halves. Pericentral node exists only if and only two sequences are paired intermetrically. It is a point for pericentral E- rotation and F-rotation. See table 9 and 10.

**The Central Node:** Denoted by ' $C_n$ '. It describes that point of the symmetrical plane or axis. It is the midpoint that divides a sequence or two paired sequences into two equal halves. It is the node and point for central rotation. The nodal point may be monocentric (as found with odd-totaled nodality) or dicentric (as found in even-totaled nodality). See Table 9 and 10.

**Nodality:** Denoted by ' $N$ ' is the total number of existing nodes in a given distribution. Nodality directly correlates with the number of elements. Respect to the central limit theorem, the high nodality promotes the dimension of similarity scores within or between entities. See Table 9 and 10.

## OPTINALYSIS

**14.1 Symmetry coefficient**

The Kabirian coefficients of symmetry and similarity ( $K_c$ ) are values that quantify the magnitude and direction of balances or imbalances in the geometrical, geostatistical and statistical distribution of sequence elements and its co-elements about a symmetric plane. It may exist in two value outcomes (from to central rotation) which translate the same significance level. It is calculated by intrametrically or intermetrically associating the quantitative scale's unit ( $r_n$ ) with the variables/elements ( $a_n$ ), or ( $b_n$ ) and ( $c_n$ ) to generate a sequence of function called scalements that moves discretely or continuously in a space with or without influence of co-elements ( $d_n$ ) and/or ( $e_n$ ) with the main elements ( $p_n$ ), from a mid-point(s) or symmetrical line or origin, called the central node as described in Table 1 below:

**Table 9:** Scalement generated function of elements intrametrically

QS-Unit ( $r_n$ )	Element ( $a_n$ )	Scalement Function $r_n (a_n + a_0^* + a'_n)$	Node ( $N_n$ )	Remarks
$r_1$	$a_1$	$(r_1 \times a_1)$	$N_1$	
$r_2$	$a_2$	$(r_2 \times a_2)$	$N_2$	
$r_3$	$a_3$	$(r_3 \times a_3)$	$N_3$	Pericentral node
$r_4$	$a_4$	$(r_4 \times a_4)$	$N_4$	
$r_5$	$a_5$	$(r_5 \times a_5)$	$N_5$	
$r_6$	$a_0^*$	$(r_6 \times a_0^*)$	$N_6$	Central node
$r_7$	$a'_5$	$(r_7 \times a'_5)$	$N_7$	
$r_8$	$a'_4$	$(r_8 \times a'_4)$	$N_8$	
$r_9$	$a'_3$	$(r_9 \times a'_3)$	$N_9$	Pericentral node
$r_{10}$	$a'_2$	$(r_{10} \times a'_2)$	$N_{10}$	
$r_{11}$	$a'_1$	$(r_{11} \times a'_1)$	$N_{11}$	
$\sum(r_n)$	$\sum(a_n + a_0^* + a'_n)$	$\sum r_n (a_n + a_0^* + a'_n)$		

Then, the Kabirian coefficient of similarity/symmetry that exists within the distribution of  $a$  elements is given by the eq. (1) below. This is what quantifies intrametric symmetry/similarity.

$$K_c = \frac{\sum(r_n)}{N} \times \frac{\sum(a_n + a_0^* + a'_n)}{1} \times \frac{1}{\sum r_n (a_n + a_0^* + a'_n)} \quad (1.1)$$

$$K_c = \frac{\sum(r_n)}{N} \times \frac{\sum(a_n + a_0^* + a'_n)}{\sum r_n (a_n + a_0^* + a'_n)} \quad (1.2)$$

## OPTINALYSIS

**Table 10:** Scalement generated function of elements intermetrically

QS-Unit ( $r_n$ )	Elements ( $a_n$ )	Scalement Function $r_n (a_n + c_0^* + b_n)$	Node ( $N_n$ )	Remarks
$r_1$	$a_1$	$(r_1 \times a_1)$	$N_1$	
$r_2$	$a_2$	$(r_2 \times a_2)$	$N_2$	
$r_3$	$a_3$	$(r_3 \times a_3)$	$N_3$	Pericentral node
$r_4$	$a_4$	$(r_4 \times a_4)$	$N_4$	
$r_5$	$a_5$	$(r_5 \times a_5)$	$N_5$	
$r_6$	$c_0^*$	$(r_6 \times c_0^*)$	$N_6$	Central node
$r_7$	$b_5$	$(r_7 \times b_5)$	$N_7$	
$r_8$	$b_4$	$(r_8 \times b_4)$	$N_8$	
$r_9$	$b_3$	$(r_9 \times b_3)$	$N_9$	Pericentral node
$r_{10}$	$b_2$	$(r_{10} \times b_2)$	$N_{10}$	
$r_{11}$	$b_1$	$(r_{11} \times b_1)$	$N_{11}$	
$\sum(r_n)$	$\sum(a_n + c_0^* + b_n)$	$\sum r_n (a_n + a_0^* + a'_n)$		

Then, the Kabirian coefficient of similarity/symmetry that exists between the two paired sequences,  $a_n$  and  $b_n$  is given by eq. (2) below. This is what quantifies intermetric symmetry/similarity.

$$K_c = \frac{\sum(r_n)}{N} \times \frac{\sum(a_n + c_0^* + b_n)}{1} \times \frac{1}{\sum r_n (a_n + a_0^* + a'_n)} \quad (2.1)$$

$$K_c = \frac{\sum(r_n)}{N} \times \frac{\sum(a_n + c_0^* + b_n)}{\sum r_n (a_n + a_0^* + a'_n)} \quad (2.2)$$

**What symmetry coefficient informs About**

- Tells whether a distribution is geometrically, geostatistically, and statistically symmetrical or asymmetrical.
- Shows the level, nature and direction of distribution imbalances.
- Allows for the calculation of unknown variable.
- Allows for the calculation of probability of similarity/symmetry.
- Allows for the calculation of probability dissimilarity/asymmetry.

**14.2 Confidence level (Probability value) of similarity**

The probability level of similarity or symmetry that exists between the two comparing intrametric or intermetric elements can be calculated by the general formula below:

Suppose  $r_n = 1, 2, 3$ ;  $p_2(b_1) = 1$  or  $100$ ;  $N_v = 0$ ;  $d_{p1, p2} = 1$ ;  $e_{p1, p2} = 1$ ; and  $p_1(a_1) = \text{unknown}$ ; for a simple dinodic and bivariate Optinalysis (Table 11). These parameters are uniform for all multivariate probabilities.

## OPTINALYSIS

**Table 11:** Bivariate Optinalysis under some constant parameters

QS-Unit ( $r_n$ )	Elements ( $p_n$ )	Co-elements ( $d_n$ )	Co-elements ( $e_n$ )	Resultant Element by Geometrical Approach $a_n = (p_n \times \Delta d_n \times \Delta e_n)$	Scalment Function $r_n(a_n + c_0^* + b_n)$
1	$x$	1	1	$a_1 = (x \times 1 \times 1)$	$(x \times 1)$
2	0	0	0	$c_0^* = (0)$	$(2 \times 0)$
3	1 or 100	1	1	$b_1 = (1 \times 1 \times 1)$ or $b_1 = (100 \times 1 \times 1)$	$(1 \times 1)$ or $(1 \times 100)$
$\sum(r_n)$ = (6)				$\sum(a_n + c_0^* + b_n)$ = $(1 + 0 + x)$ or $(100 + 0 + x)$	$\sum r_n(a_n + c_0^* + b_n)$ = $(x + 0 + 1)$ or $(x + 0 + 100)$

By substituting these variables into equation 2

$$K_c = \frac{2(x+1)}{x+3} \text{ or } K_c = \frac{2(x+100)}{x+300}$$

By making  $x$  the subject of the formula, we now have

$$P_{Sim. - value} = \frac{(2 \times 1) - (3 \times 1 \times S_c)}{K_c - 2} \quad (3.1)$$

$$\% Dsim. = \frac{(2 \times 100) - (3 \times 100 \times S_c)}{K_c - 2} \quad (3.2)$$

Equation (3) is appropriate if  $K_c$  is between 1 and tend to 0.66667

In the other turn, suppose  $r_n = 1, 2, 3$ ;  $p_1(a_1) = 1$  or  $100$ ;  $N_v = 0$ ;  $d_{p1, p2} = 1$ ;  $e_{p1, p2} = 1$ ; and  $p_2(b_1) = \text{unknown}$ ; for a simple dinodic and bivariate Optinalysis (Table 12). These parameters are uniform for all multivariate probabilities.

**Table 12:** Bivariate Optinalysis under some constant parameters

QS-Unit ( $r_n$ )	Elements ( $p_n$ )	Co-elements ( $d_n$ )	Co-elements ( $e_n$ )	Resultant Element by Geometrical Approach $a_n = (p_n \times \Delta d_n \times \Delta e_n)$	Scalment Function $r_n(a_n + c_0^* + b_n)$
1	1 or 100	1	1	$a_1 = (1 \times 1 \times 1)$ or $a_1 = (100 \times 1 \times 1)$	$(1 \times 1)$ or $(1 \times 100)$
2	0	0	0	$c_0^* = (0)$	$(2 \times 0)$
3	$x$	1	1	$b_1 = (x \times 1 \times 1)$	$(3 \times x)$
$\sum(r_n)$ = (6)				$\sum(a_n + c_0^* + b_n)$ = $(1 + 0 + x)$ or $(100 + 0 + x)$	$\sum r_n(a_n + c_0^* + b_n)$ = $(1 + 0 + 3x)$ or $(100 + 0 + 3x)$

By substituting these variables into equation 2

$$K_c = \frac{2(1+x)}{3x} \text{ or } K_c = \frac{2(100+x)}{300x}$$

## OPTINALYSIS

$$P_{Sim. - value} = \frac{(2 \times 1) - (1 \times S_c)}{(3 \times K_c - 2)} \quad (4.1)$$

$$\% Sim. - value = \frac{(2 \times 100) - (100 \times S_c)}{(3 \times K_c - 2)} \quad (4.2)$$

Equation (3) is appropriate if  $K_c$  is between 1 and tend to 2

## 14.3 Confidence level (Probability value) of dissimilarity

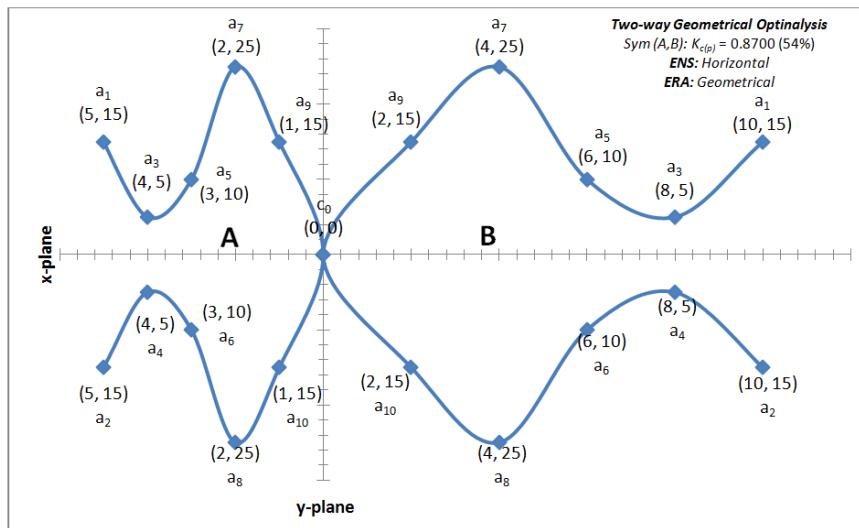

$$P_{Dsim. - value} = (1 - P_{Sim. - value}) \quad (5.1)$$

$$\% Dsim. - value = (100 - \% Sim. - value) \quad (5.2)$$

## 15.0 The Role of Co-elements in Harmonizing Size Variations and Dimensional Symmetry Detection

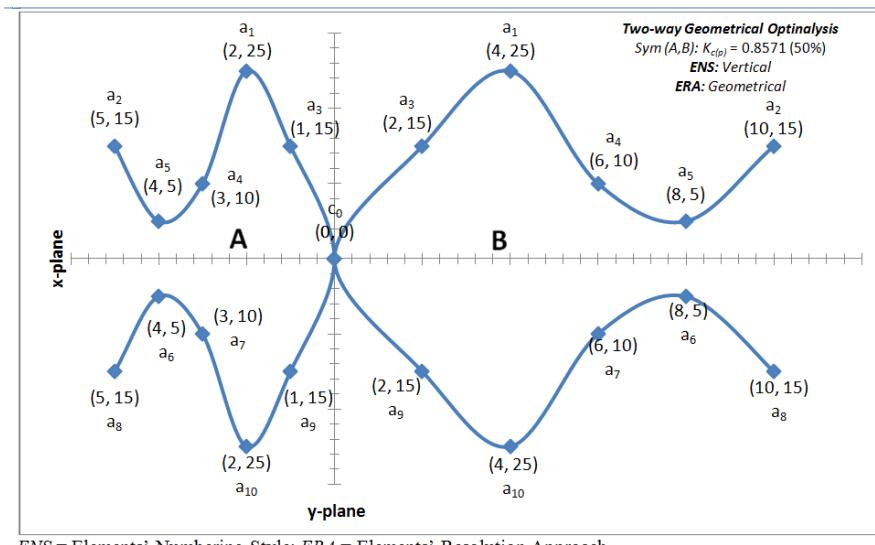

Co-elements directly and dependently affect the geometric, geostatistical, and as well as the statistical characteristics and distribution of elements of a sequence.

Suppose we have two geometrical structures (shown in Figures 24-25) with same y-coordinates but differs by two folds in their x-coordinates. Logically, we can say that shape A is two times (x2) bigger in size than shape B with an expected probability P-value) equals to 0.5 (50%). Following two-way geometric Optinalysis, the two structures are similar by 54% using the horizontal numbering style and also 50% using the vertical numbering style, as both cases shown on Figures 24 and 25 respectively. Therefore, from these two cases, we can conclude that the best and appropriate numbering style is the one that establishes a clearer pericentral orientation about a symmetrical plane.

**Figure 24:** The geometrical Optinalysis of two different sized structures

## OPTINALYSIS

ENS = Elements' Numbering Style; ERA = Elements' Resolution Approach

**Figure 25:** The geometrical Optinalysis of two different sized structures

### 16.0 Types of Symmetry Detection by Optinalysis

**Intrametric symmetry detection:** It describes the object symmetry explained by Mardia *et.al.*, (2000) which demonstrates symmetry within elements (points) of same structure or entity.

**Intermetric symmetry detection:** It describes the matching symmetry explained by Mardia *et.al.*, (2000) which demonstrates symmetry between elements (points) of different structures or entities.

### 17.0 N-way Symmetry Detection by Optinalysis

**One-way Optinalysis:** Quantify symmetry of set of elements (e.g set of magnitudes) only without the contribution of any co-element. A typical example is the symmetry of a random distribution of elements of a set.

**Two-way Optinalysis:** Quantify symmetry of set of elements (e.g set of magnitudes) and in association with any one of their co-elements. A typical example is the two dimensional symmetry of a vector (e.g shape symmetry in two dimensions).

**Three-way Optinalysis:** Quantify symmetry of set of elements (e.g set of magnitudes) in association with any two of their co-elements. A typical example is the three dimensional symmetry of a vectors (e.g shape symmetry in three dimensions).

### 18.0 Types of Optinalysis

**Geometrical Optinalysis:** Is the analysis that preserves the inherent geometric positions of all elements of a data set. This approach is more likely to be useful for geometric shape/pattern analysis.

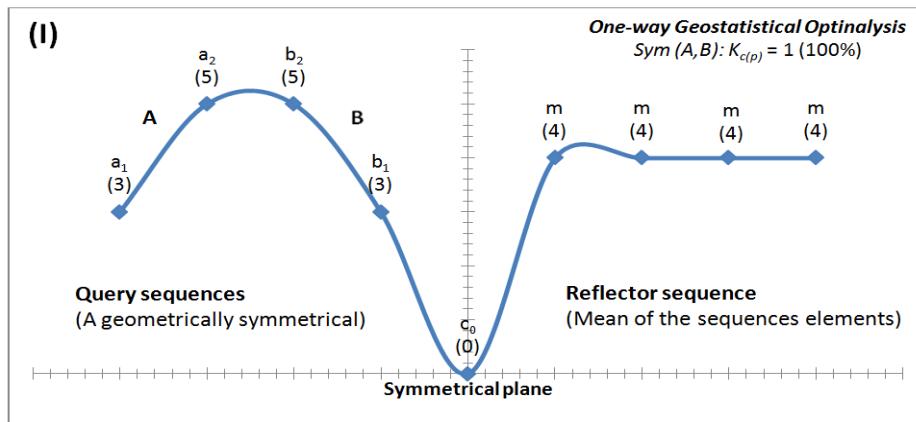

Intrametric Geometric Optinalysis requires no pairing style to be chosen, because only one sequence is involved. But the Intermetric Geometric Optinalysis requires a suitable selection of a pairing style between the two sequences. In this case, selecting the most sensitive region toward the head (head-to-head pairing style) may not give same result if also considered toward the tail (tail-to-tail pairing style) except for geometrically eu-symmetrical distributions which are stable under any pairing style (i.e, under E-rotation). Where elements (observations) are in replicate measurements, the sequence order within the replicates must be disregarded by re-arranging the elements into a define sequence order (ascending or descending order). It is called type (I)

## OPTINALYSIS

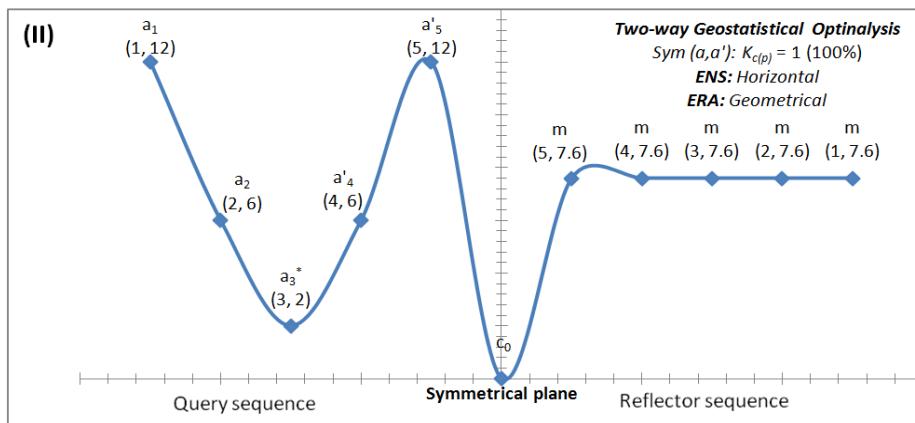

geometrical Optinalysis if ascending order of replicates is used, while it is called type (II) geometrical Optinalysis if descending order of replicates is chosen. Some typical examples of geometric Optinalysis are in Figure 1-11 and 12-23.

**Geostatistical Optinalysis:** Is the analysis that preserves the inherent geometric positions of all elements of a data sequence and in respect to a statistical tendency of the distribution mean or median or mode. The geometric pattern of the sequence distribution is reflected **with/by** a headless and tailless sequence of its representing mean, median, mode or any other value of interest, as shown in figure 26-29.

Similar with Geometric Optinalysis, Intrametric Geostatistical Optinalysis requires no pairing style, because only one sequence is involved. But the Intermetric Geostatistical Optinalysis requires a suitable selection of pairing style between two sequences. In this case, selecting the most sensitive region toward the head (head-to-head pairing style) may not give same result if also considered toward the tail (tail-to-tail pairing style) except for geometrically eu-symmetric distributions which are stable under any pairing style (i.e, under E-rotation). Where elements (observations) are in replicate measurements, the sequence order within the replicates must be disregarded by re-arranging the elements into a define sequence order (ascending or descending order). It is called type (I) geostatistical Optinalysis if ascending order of replicates is chosen, while it is called type (II) geostatistical Optinalysis if descending order of replicates is used.

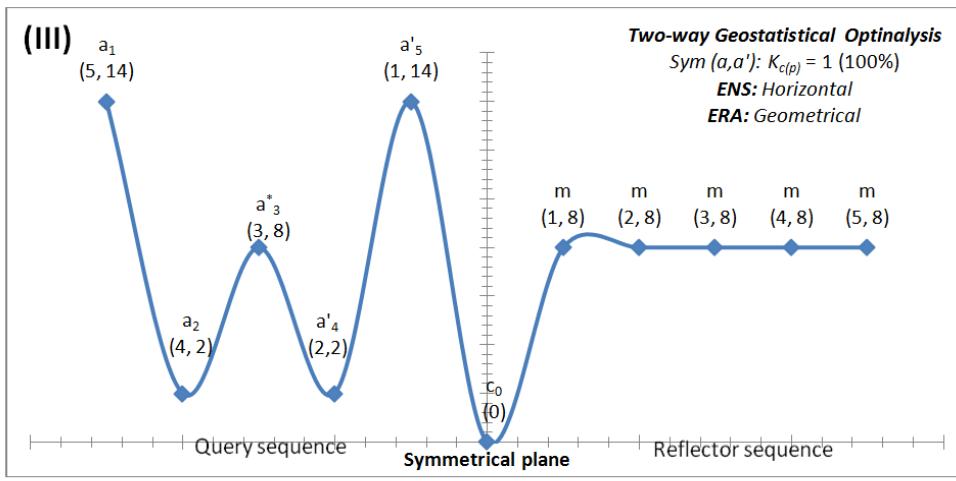

**Figure 26:** One-way Geostatistical Optinalysis (Paired Head-to-head Intermetrically)

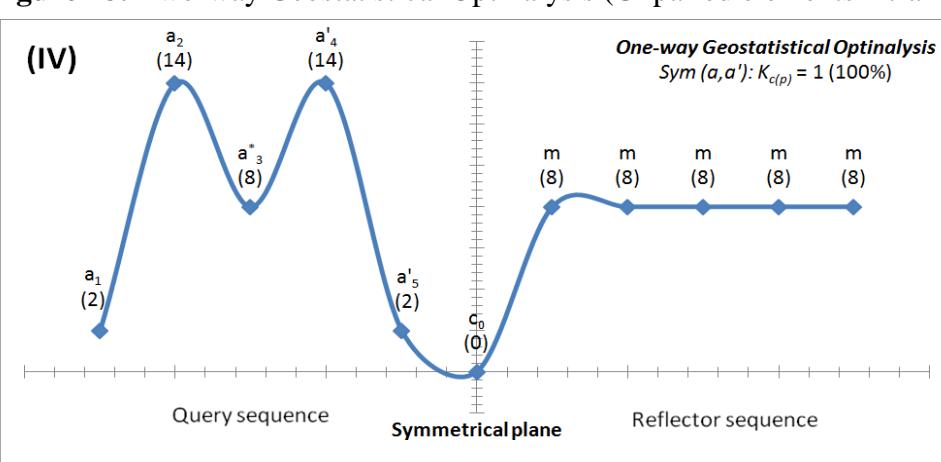

*ENS = Elements' Numbering Style; ERA = Elements' Resolution Approach*

**Figure 27:** Two-way Geostatistical Optinalysis (Unpaired elements intrametrically)

## OPTINALYSIS

**Figure 28:** Two-way Geostatistical Optinalysis (Unpaired elements intrametrically)

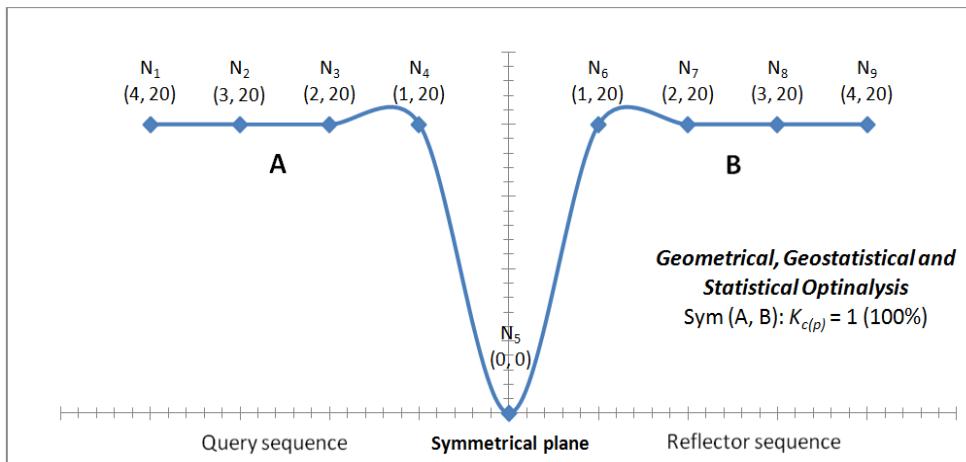

**Figure 29:** One-way Geostatistical Optinalysis (Unpaired elements intrametrically)

**Statistical Optinalysis:** Is the analysis that disregards the inherent geometric positions of all elements of a data sequence, but assume it own logical sequence. This approach is more likely to be used for the analysis of experimental data.

Unlike with Geometric and Geostatistical Optinalysis, both the Intrametric and Intermetric Statistical Optinalysis requires no pairing style, but all the elements of the sequence(s) are reorganized in ascending or descending order. Both the ascending and descending order of reorganization give different results. It is called type (I) statistical Optinalysis if ascending order of all the elements is chosen, while it is called type (II) statistical Optinalysis if descending order of all the elements is used.

Note that, a sequence with uniformly distributed elements, either in magnitude only (i.e., one-way Optinalysis) or both in magnitude and directions (i.e., two-way or three-way Optinalysis) is geometrically, geostatistically and statistically symmetrical absolutely. See Figure 30.

## OPTINALYSIS

**Figure 30:** Optinalysis of uniformly distributed elements

### 19.0 Geometrical Measure of Skewness by Optinalysis\

Skewness measure is one of the very important aspects of statistics. In this subsection, a new method is presented on some step-by-step approach to skewness detection using the principles of Optinalysis.

**Step 1:** Identify or obtain the data to be analyzed.

**Step 2:** Re-organize or sort the data into ascending or descending sequence order.

**Step 3:** Calculate the mean of the distribution.

**Step 4:** Compute the squared mean difference of each element of the data set and use it as the resultant element for geometrical Optinalysis. The sequence order must be maintained geometrically.

**Step 5:** Using geometrical Optinalysis method, calculate the Kabirian coefficient of symmetry (similarity), and the probabilities or percentages.

### 19.1 Interpreting the Result of Skewness Measure

Obtaining Kabirian coefficient equals to 1,  $>1$ ,  $<1$  indicates zero skewness, negative skewness (more heaviness below the mean of the distribution), positive skewness (more heaviness above the mean of the distribution) respectively. The probabilities or percentages obtained are the significance level at which the distribution of the elements or the deviation of elements is symmetrical about a mean. Figure 31 is an illustration of a distribution of integers (1,2,3,4,5, 6,7,8,9,10,11) with a zero skewness, look symmetrical about the mean value of 6. The geometrically optinalytic approach of skewness detection described here gives a similar result with the standard method with zero skewness.

## 20.0 Some Features of a Geometrical and Geostatistical Distributions

Geometrical and geostatistical distribution exhibit these characteristics, as follows:

### 20.1 Central modulation and Normalization

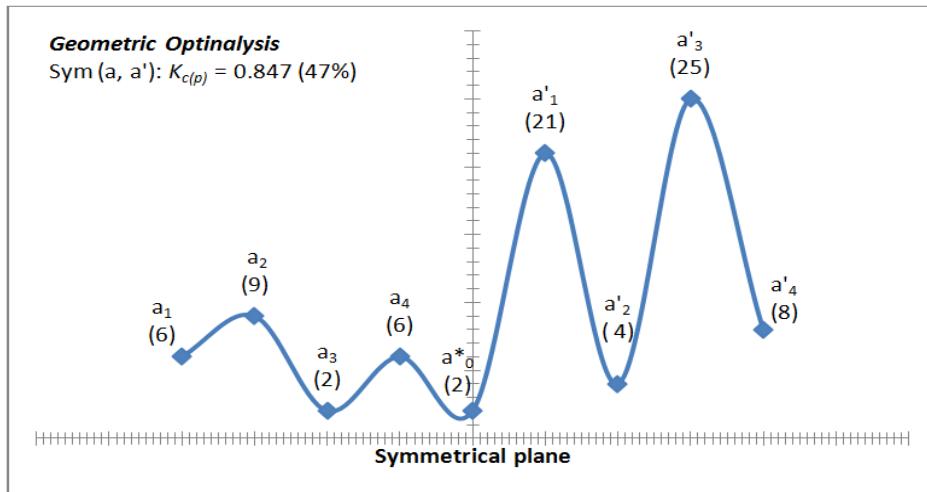

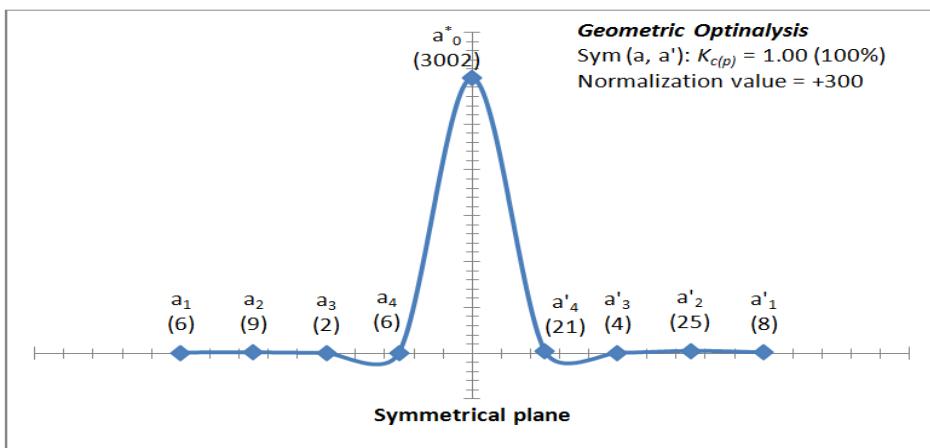

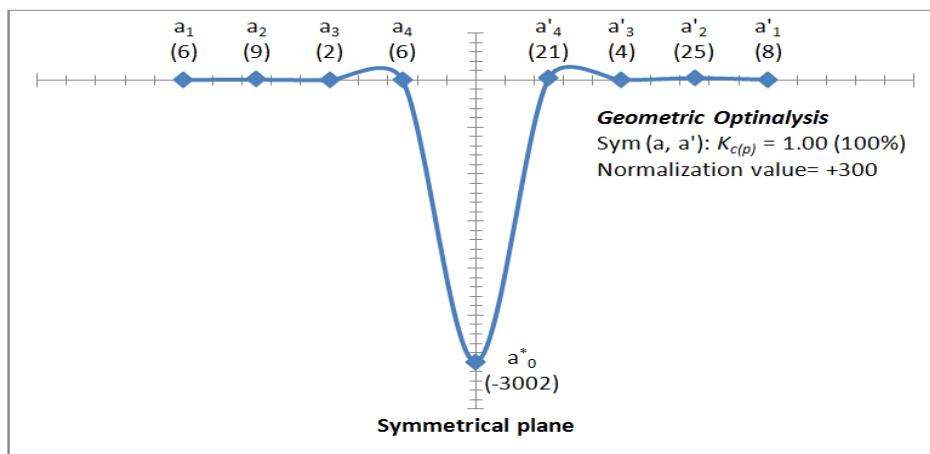

Central modulation is refers to a deliberate positive or negative increase in magnitude of the central node's element of a given geometrical or geostatistical distribution. A geometrically or geostatistically symmetrical distribution remains symmetrically stable under any magnitude of central modulation. This explain that a geometrically or geostatistically symmetrical distribution is very flexible and stable to any limit of central modulation.

Asymmetrical distribution of elements can be transformed symmetrical if the central node is positively or negatively modulated to a certain minimum magnitude called a normalization value. The minimum value that is required to normalize asymmetrical distribution symmetrical is refers to as normalization value ( $\pm Nv$ ). Therefore, central modulation promotes unimodality, minimizes the skewness of a data, and thus promotes unification of Kabirian coefficient similarity/symmetry. See Figure 32-34 for visually illustrative examples.

$$\bigwedge_w^{(\pm Nv=0)} : \int_{c(p)}^{\epsilon(A)} = 0.847(47\%)$$

$$\bigwedge_w^{(\pm Nv=3000)} : \int_{c(p)}^{\epsilon(A)} = \sim 1(\sim 100\%)$$

## OPTINALYSIS

**Figure 32:** Asymmetrical distribution**Figure 9:** Transformed normalized distribution (By positive modulation)**Figure 33:** Transformed normalized distribution (By positive modulation)**Figure 34:** Transformed normalized distribution (By negative modulation)

## OPTINALYSIS

## 20.2 Critical switch points:

A geometrically or geostatistically symmetrical distribution is said to be absolutely nullified if the sum of all sequence elements is equal to zero. It is notated by the expression below.

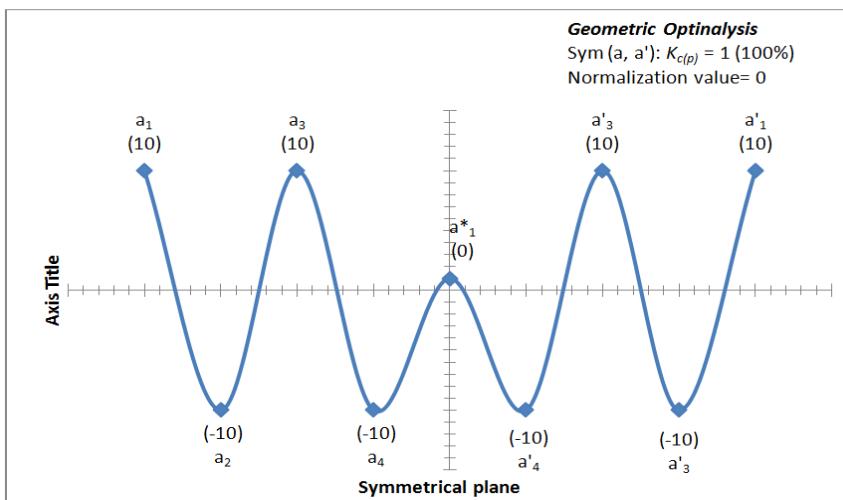

$$\bigwedge_{W \text{ or } B}^{(\pm Nv=0)} : \in (A + A') = 0 \quad \int_{c(p)}^{\epsilon(A)} = 0 (\pm 100\%)$$

The absolutely nullified symmetrical distribution can be absolutely activated if central node's element is modulated by any fraction of natural number ( $\mathbb{N}$ ). It is notated by the expression below:

$$\bigwedge_{W \text{ or } B}^{(\pm Nva=\mathbb{N})} : \in (A + A') = 0 \quad \int_{c(p)}^{\epsilon(A)} = 1 (100\%)$$

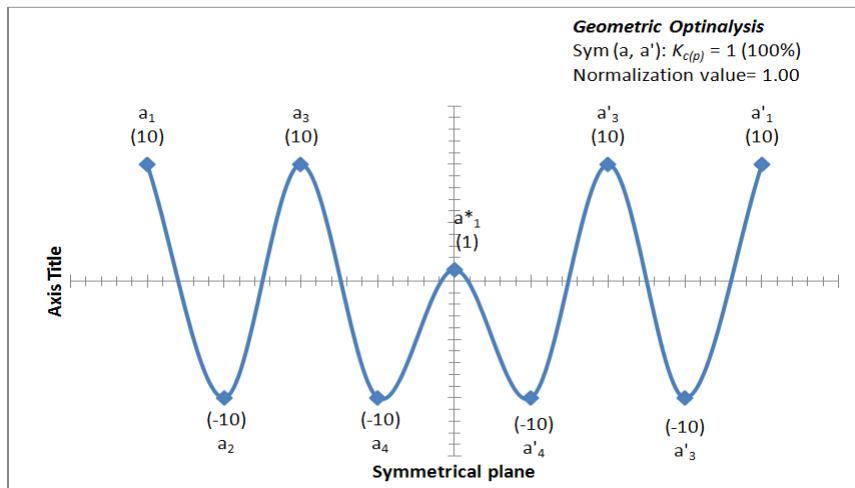

The value required to nullify or activate a nullified symmetrical distribution is what define a nullification ( $Nv_n$ ) and normalized activation ( $Nv_a$ ) value respectively. The target site effective for nullification is the central node.

Therefore, if the Kabirian coefficient of symmetry/similarity of a given distribution of elements is equal zero, then, further cross check is necessary to confirm whether the distribution is nullified symmetrical or is asymmetrical by the following approaches: a) normalized activation, b) visualization of pattern orientation, c) summation checking. Note that graphic visualization approach is not sufficient to make a conclusion, because pseudo-symmetrical distributions resemble the asymmetrical once visually. For a nullified symmetrical distributions, the zero Kabirian coefficient resume to unity (1) by a simple normalized activation at the central node, graphically look symmetrical and the total sum of all elements is equal to zero. See Figure 25-38.

## OPTINALYSIS

**21.0 Application, Simulation and Discussions**

This section will provide a practical example of how Optinalysis is suitable for analysis of socio-demographic data, demographic, social, and psychometric data.

**21.1 Example 1: Socio-demographic Data (I)**

Table 13 Presented the calculated socio-demographic positions and frequencies of the sampled 1,000 individuals from a given population of feminine socio-demographic kingdom of the third socio-demographic clades, within the upper socio-demographic group of class 1 socio-demographic status (Abdullahi, 2019b).

The data distribution was first tested for the level and direction of skewness using a Graphad Prism software of 8.0.2 version, and then by the geometrical Optinalysis. The results in Table 14 shows that Optinalysis is a more advance approach over the method used in the software, because it provide further detail about the significance level of skewness. Both the two methods shows the same direction of skewness.

The results of Optinalysis in Table 14 shows that all the frequency of individuals in each of the seven populations A-G are significantly dissimilar ( $P>0.95$ ) statistically, geostatistically and geometrically except population E which is significantly similar ( $P>0.95$ ) geostatistically. Optinalysis, paired T-test, and Tukey's multiple comparisons were used to separate the means. The result of the multiple comparison in Table 15-18 shows that Optinalysis is more sensitive and detected a significant dissimilarity ( $P>0.95$ ) statistically, geostatistically and geometrically, which otherwise T-test and Turkey's multiple comparisons has not detected any differences at ( $P<0.05$ ) equivalence.

**21. 2 Example 2: Socio-demographic Data (II)**

Table 19 presented the composition of socio-demographic attributes of two populations from the sample 500 individuals. The order and sequence of the attributes is based on the theory of Abdullahi (2019b). Geostatistical Optinalysis was used to compare the frequency distribution against the population mean frequency. The result of Optinalysis shows that the frequency distribution between the two populations A and B is significant dissimilar ( $P>0.95$ ) geostatistically.

## OPTINALYSIS

**Table 19:** Frequency Composition of Populations and their Geostatistical Significance

	Population A	Population B
<b>(H)Gender</b>		
Female	2,153,943	3,333,252
Male	1,267,026	3,508,686
<b>Age</b>	3,420,969	6,841,938
<i>Childhood</i>		
0-3	245,587	491,174
4-6	274,724	519,448
7-9	324,567	679,134
<i>Adolescence</i>		
10-15	478,234	956,468
16-20	486,345	972,690
21-25	487,468	974,936
<i>Adulthood</i>		
26-40	356,234	752,468
41-55	373,787	707,574
Above 56	394,023	788,046
<b>Education</b>		
None	2,443,870	1,872,740
Student	935,764	4,871,528
Teacher	27,879	70,758
Researcher	13,456	26,912
<b>Occupation</b>		
Unemployed	2,473,049	4,006,098
Lower scale	675,345	1,850,690
Middle scale	256,898	913,796
Higher scale	15,677	71,354
<b>(T)Marital status</b>		
Bachelor	2,638,687	5,277,374
Divorced	16,468	52,936
Widow(er)	2,346	9,692
Married	763,468	1,501,936

**One-way Geostatistical Optinalysis Between Population A and B**

Kc-value	0.91838
P <sub>Sim.</sub> -value	0.69817
P <sub>Dsim.</sub> -value	0.30183

Number of individuals in each population A and B are 3,420,969 and 6,841,938 respectively.

## OPTINALYSIS

## 21.3 Example 3: Psychometric Data (I)

Table 20 Presented the calculated Value Priority Scores by Kab's Value Survey (KVS) and the frequency of individuals from a given socially dynamic population with different value orientation toward a particular value attribute. (Abdullahi, 2019a). Two-way Optinalysis (using  $vps^{-1}i$  as the element, and the individuals' relative frequency as the co-element) was used to account for the significance of the variation in value practice in the populations. The results of two-way Optinalysis in Table 21 shows that the distribution of Value priority scores (VPS) in all the seven populations A-G are significantly dissimilar ( $P>0.95$ ) statistically, geostatistically and geometrically.

One sample t-test and Optinalysis was also used to test if the populations' distribution of value priority scores was significantly similar with (represent) the reference standard code of value practice (theoretical mean) of 72  $vps^{-1}p$  ( $0.72vps^{-1}i \times 1,500$  individuals =  $1080/15 = 72$ ). The results presented in Table 22 shows that Optinalysis and one sample t-test provided almost same conclusion, but Optinalysis with the highest sensitivity.

**Table 20:** Populations' Value Priority Scores Using Kab's Value Survey

Kab's Value Survey (KVS)															
	5 (Every D & N)			4 (Every DL or DN)			3 (Every W)			2 (Every M)			1 (Every Y)		
	3-4 times	2-3 times	1-2 times	3-4 times	2-3 times	1-2 times	3-4 times	2-3 times	1-2 times	3-4 times	2-3 times	1-2 times	3-4 times	2-3 times	1-2 times

**21.6 Example 6: Words Semantics**

Spell checking is one of the important measure of students semantic performane. The word “Psychology” was differently written by students and the results were qualitatively compared with the correct word for similarity measure. The word sequence is numerically transformed by Kabirian (A) and Kabirian (B) Algorithmic transformation appraoach. For Kabirian (A) Algorithmic transformation appraoach, typ II resolution rule was used to for each polymorphic clusters. Geometric Optinalysis and cosine similarity designed online at <https://glench.github.io/fuzzyset.js/> was used to calculate the percentage similarity and the similarity scores respectively. The results in Table 25-27 show that Optinalysis is the best approach over cosine similarity measure because it express a broad range of arguments, methodologies and results, more probablistic in conclusion, specific and sensitive to mismatchness.

## OPTINALYSIS

**21.7 Example 7: Genetics and Bioinformatics (Homology searches)**

Tables 28-32 presented are the set of problems regarding nucleotide base and protein sequences comparisions. The sequences were numerically transformed by Kabirian (A) and Kabirian (B) Algorithmic transformation appraoaches. For Kabirian (A) Algorithmic transformation appraoach, type I resolution rule was used to for each of the polymorphic clusters. Geometric Optinalysis was used to calculate the percentage similarities. Moreover, an online BLAST software at a link <https://blast.ncbi.nlm.nih.gov/Blast.cgi> was used to perform pairwise alignment and obtained the blasted results of percentage idenentity and similarity, and the Needleman-Wunsch score. The results show that Optinalysis is more advanced method, beecause it express a broad range of methodologies and results (See Tables 28-32 for the different results from different Kabirian transformation algorithms used). Optinalysis is more specific to the data sequence geometry (Seen Tables 28-32) and very sensitive to changes in magnitude and position, sequence rearrangements, sequence length, may combine the computation of match, mismatch and gab at same time, or each can be seperately quantified. The adopted methods of identity and similarity detection used in the software (the BLAST algorithm) considered the whole aligned sequences as a one cluster for match or gab frequency scores, and this lack of clustering distinguishes it from Kabirian (B) algorithmic transformation, in addition to Optinalysis compare among the sequences rather than by simple fraction.as use in BLAST.

Moreover, despite the disregardness of the BLAST algorithms to the sequence geometry, even the Needleman-Wunsch algorithm is some times bias. Bias in the sanse that two distinctly different sequence may have same results as pairwise compared to a same query sequence.

However, Optinalysis can be a good choice for numerical chromosomal abberations due to deletion, duplication, translocation, and inversion. Optinalysis further revealed that organisms with short genomic sequence are more sensitive to mutation by even few nuclotide changes than those organisms with very lengthy genomic sequence. This explain why prokaryotic DNA/RNA are more sensitive to mutation and immensely used in mutation study, because the mutagenic effects are more express phenotypically even if the mutation rate is low. For general mutation detection, Kabirian (A) algorithmic transformations can be suitable , but for the case of deletion, duplication, inversion and translocation each seperately, Kabirian algorithmic transformations can be used.

In bioinformatics, lack of statistical confidence estimation, alignment errors, low specificity and sensitivity, are some of the problems associated with homology search algorithms (Lunter *et. al.* 2008). Therefore, Optinalysis has solved the problem of lack of confidence estimates which other methods have failed to explain the result in a probabilistic manner (Lunter *et. al.* 2008). Statistical confidence estimation, and geometric specificity and sensitivity is one of the grand acheivement using Optinalysis to compare among a pairwise set of nuclotide and protein sequences. Other algorithms such BLAST is not geometric analytically. The accuracy of the result following Optinalysis depends on the correctness and effectiveness of the sequence pairwise alignments. What among the homology search problems Optinalysis have failed to solve include an alignment errors.

## OPTINALYSIS

**21.8 Example 8: Ecological Data**

Ecologists are very interested in any quantification that measure the abundance and spread of biological species within an ecosystem. Table 32 recorded the frequency of six (6) species per unit cluster of  $1000m^2$  area, in a systematic order moving A-H to the left and A'-H' to the right from an origin "O". Two-way Optinalysis (Species freq. as the element  $\times$  area in  $m^2$  as the co-element) was used to calculate the geometric, geostatistical and statistical similarity in the species abundance between each cluster. The Optinalysis results in Tables 34-36 shows that the distribution and abundance of the species are significantly ( $P>0.95$ ) dissimilar geometrically, geostatistically and statistically between the studied clusters.

**Table 33: Ecological Survey Data**

Area ( $\times 10^3 m^2$ ) Clusters	1 (H)	1 G	1 F	1 E	1 D	1 C	1 B	1 A <sup>(T)</sup>	0 O	1 (T)A'	1 B'	1 C'	1 D'	1 E'	1 F'	1 G'	1 H <sup>(H)</sup>

## OPTINALYSIS

## 21.9 Example 9: Experimental Data (I)

Tables 37 and 38 recorded the effect of substance addition at different concentrations aim to promote the metabolism of a given living process. The result was measured in three replicates. The Optinalysis calculated results were compared with the ANOVA result using graphad Prism, version 8.0.2. Comparatively, statistical Optinalysis shows some similarities in results with ANOVA and Turkey's multiple as shown in Tables 39-41.

## OPTINALYSIS

## 21.10 Example 10: Experimental Data (II)

An illustration below represent a balanced meter rule (100cm in length) on a pivot at the central gravity (50cm mid-point). Different set of masses where placed at different points distanced away 25cm and 50cm from the pivot. Given that masses on X and Y points where used as tabulated in the Table 39.

Note:  $D_n$  = Displacements; X and Y are masses; and C = Central mid-point (at the pivot)

**Figure 39:** Moment of Forces about a Point

Two-way geometrical Optinalysis (masses as the elements, x and y, and the internodal distance = 25cm as the co-element) was used here to calculate the percentage balance (symmetry/similarity) between the right and the left suspended masses. The results attached in Table 43 shows that Optinalysis confirm a symmetrically significant if total clockwise moment and total anticlockwise moments are equal about central pivot. Using the principle of moment, it is justified that Optinalysis principally operates by the principles of moment and reflection, and in addition it presented an advanced approach for calculating the level of balanced or imbalances by quantifying the probability or percentage symmetry or similarity that exists between the exerting masses about a central pivot point.

**Table 43:** Results of Optinalysis of the Moment Designed Data

## OPTINALYSIS

**21.11 Example 11: Experimental Data (III)**

Table 44 recorded the 2theta angle and the diffraction intensity from XRD machine. Using two-way geometric Optinalysis Optinalysis (diffraction intensity as the elements and the internodal distance = 5 units of 2theta angle as the co-element), conclude which of the samples are closely similar to sample A?. The Optinalysis results in Table 45 by multiple comparison shows that sample B is significantly ( $P>0.95$ ) similar to sample A geometrically while D are not similar geometrically ( $P>0.95$ ).

**Table 44:** 2Theta Angles and the Diffraction Intensity of Samples

## OPTINALYSIS

**21.12 Example 12: Morphometric Shape Data (I)**

In this paper, most of the illustrative examples used are geometrical in sense. Specifically, in Biosystematics, leaf geometric morphometry is an essential tool in biosystematics of quantitative characters of plant species.

Table 46 recorded the partitioned leaf surface area from the left and from the right portion of the leaf lamina about a leaf's mid-ribs, as shown in Figure 40. Correspondence started from petiole base ( $A_1:B_1$ ) to the apex of the leaf ( $A_{10}:B_{10}$ ). Following head-to-head (petiole-to-petiole) pairing style and a horizontal-ups numbering style, the geometric symmetric status of the leaf from each species was computed by geometric Optinalysis, and compared with Root mean squared error (RMSE), and Areal ratio (AR) methods as described in Shi *et. al.*, (2018). The results in Tables 47 and 48 of the geometric Optinalysis and in comparison with other methods of leaf symmetry detection shows that Optinalysis is also a very suitable approach of leaf symmetry detection.

**Source:** Shi *et. al.*, (2018)

**Figure 40:** Partitioning of leaf surface area into discrete geometric marks

**21.13 Example 13: Morphometric Shape Data (II)**

Multidimensional scaling (MDS) or Euclidean distance matrix analysis plot of the male gorilla data and 13 means using Riemannian distance to form the dissimilarity matrix was calculated as explained by Dryden and Mardia (2016). The sample means for the male gorilla data was calculated to have small shape variability. There are  $k = 8$  landmarks in  $m = 2$  dimensions on  $n = 29$  male gorillas (Dryden and Mardia, 2016). In comparison to Optinalysis,

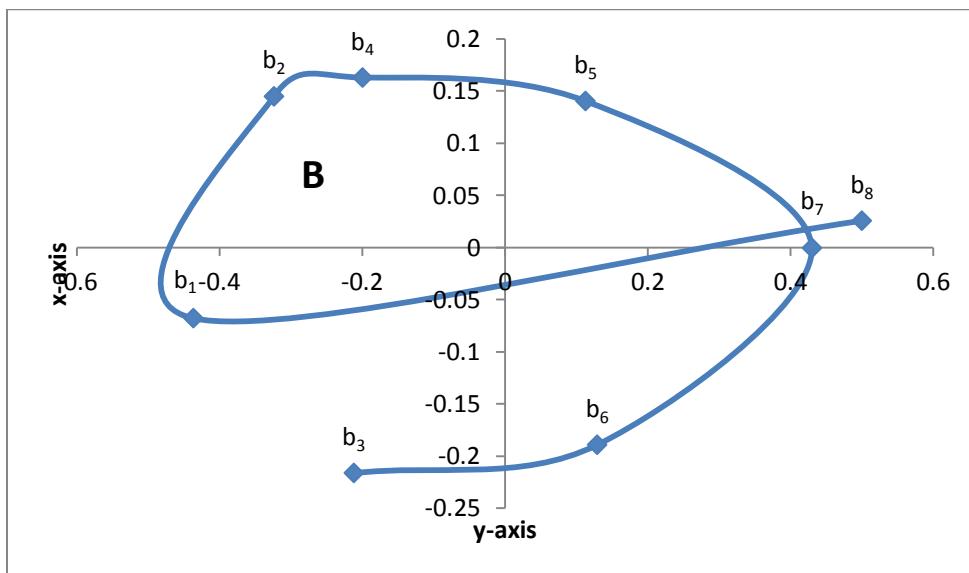

## OPTINALYSIS

the 8 landmarks were appropriately numbered by horizontal style, scale edited (on a positive scaling), paired (head-to-head, starting from  $a_1$  numbered landmark) and computed for Kabirian coefficients of similarity, percentage similarity and dissimilarity between the two shapes. The two shapes are graphically shown in Figure 41 and 42.

Following Riemannian shape distance, the two mean shapes A and B are very similar, with 0.0009 apart (Dryden and Mardia, 2016). On the other hand, following two-way geometric Optinalysis, shape A and B are significantly ( $P>0.999$  or  $P<0.00081$ ) similar geometrically with a Kabirian coefficient of similarity 0.999796 (Table 49). Therefore, the two methods have almost same conclusion, but Optinalysis is very probabilistic, more sensitive and specific.

0.999796	0.999184	0.000815	0.999287	0.997150	0.002849

**Summary**

Optinalysis can be summarized in the following items:

- Optinalysis, as method of symmetry detection, intrametrically or intermetrically computes and compares two or more multivariate sequences in an unclustered or clustered manner as a mirror-like reflection (optics-like manner).
- Elements of symmetrical structures reflect in same moment (or in same total moments) about a symmetrical plane.
- Structures can be symmetrically compared intrametrically or intermetrically and analyzed geometrically, geostatistically, and statistically.
- Lack of symmetry (asymmetry) exists when reflection is not in same moment (or total moments) about a symmetrical plane.
- Symmetry reflection can occur on one or more symmetrical planes, hence is classified as mono-planal (bilateral) or poly-planal (radial) symmetry.
- Numbering style define what symmetry plane is considered.

## OPTINALYSIS

- Symmetrical structures may or may not loss (instable and stable respectively) its symmetrical status under E-rotation, hence is classified as eu-symmetrical and pseudo-symmetrical structures.
- Each point (node) of a symmetry group has its own characteristics sensitivity, which increases away from the central node.
- Symmetry can be optinallytically detected in one-way, two-way and three-way based on the influence of the dimensional co-elements. The co-elements harmonized the variations due to other dimensional axis.
- Kabirian coefficient of symmetry or similarity is the fundamental value that explains a lot about the features and characteristics of symmetrical structures.
- Symmetry detection reflects similarity measurement.

### Acknowledgement

I thank for the motivations and encouragement received from Zahara'u Abdulhamid Bugaje and Abubakar Bello. This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

### Conflict of interest

The author declares no conflict of interest.
