14 Abstract: Patient-derived xenograft (PDX) models are created by engraftment of patients' tumor 15 tissues into immunocompetent mice. Since PDX model keep the characteristics of primary patient's 16 tumor such as gene expression profiles and drug sensitivity, it now becomes most reliable in vivo 17 human cancer model. The engraftment rate are increased with the introduction of NOD/Scid based 18 immunocompromised mice, especially, NK cell defective NOD strains such as NOD/Scid/IL2Rynu 19 (NOG/ NSG) mice and NOD/Scid/Jak3^{null} (NOJ) mice. Success ratio differs from the origin of tumor: 20 Gastrointestinal tumors tend to higher success rate and breast cancer is lower. Subcutaneous 21 transplantation is most popular method to establish PDX, but some tumor needs orthotropic or renal 22 capsule transplantation, and human hormone treatment is needed to establish hormone dependent 23 cancers such as prostate and breast cancer. PDX library with patient's clinical data, gene-expression 24 patterns, mutational status, drug responsiveness and tumor architecture will be the powerful tool 25 for developing specific biomarker and novel individualized therapy and establishing precision 26 cancer medicine.

30 1. Introduction

31 The preclinical study using animal model is essential for drug development. However, even 32 preclinical trial is successful, fewer than 10% of drug candidates was approved for market[1]. 33 Success rate of oncology field drug development has been ~5%, worst of all of field [2]. It is 34 explained that there is not appropriate animal model of human cancers. Mice tumors and human 35 cell line transplanted animal models are not always reflected the human cancer pathogenesis and 36 drug response [3], because mice and humans are considerably different [4] and human cancer cell 37 lines lost the character of original tumor[5]. National Cancer Institute (NCI, USA) recently decided 38 to retire NCI-60, a panel of 60 human cell lines from its drug screening, and use Patient-derived 39 xenograft (PDX) with these reasons [3]. PDX is established with direct engraftment of patient's 40 tumors into immunocompromised mice and maintained in vivo, which have emerged as important 41 tool for preclinical and translational research, especially to investigate the nature of tumor and drug 42 development. With the introduction of highly immunocompromised mice as recipients, PDX 43 models are now widely spread and are becoming standard "Avatar" models for cancer research.

45 2. Establishment of immunocompromised mice

46 **2.1.** Nude mice

In 1962, .first known immunocompromised mice, namely Nude mice, were discovered by Dr. Norman. R. Grist. Since the coat hair is lacking in this mice, the "Nude" nickname was given for the mice. Flanagan SP showed that nude mice also lacked thymus and Y lymphocytes are lacking in these mice[6]. Therefore they are lacking adaptive immune response including T cell mediated immune responses and antibody formation that requires helper T cells. Nude mice have been used as the recipient of human tumor xenografts since then, however, the there are limitations on transplantable human tumor cells due to intact (or rather activated) innate immunity [7].

54 2.2. SCID mice

55 In 1983, Bosma GC (Fox Chase Cancer Institute) first described severe combined 56 immunodeficient (SCID) mice lacking both functional T and B lymphocytes[8]. Since Prkdc (Protein 57 kinase, DNA activated, catalytic polypeptide: DNK-PKCs)) is lacking, V(D)J recombination does not 58 occur and B and T lymphocytes fail to mature. The engraftment efficiency of human tumor is higher 59 in SCID mice than nude mice [9]. SCID mice were first used as recipient of human hematopoietic 60 stem cells (HSCs) and peripheral blood mononuclear cell (PBMC) transplantation [10,11]. However, 61 the transplantation efficiency of human blood cells and tumor cells were not high enough, which was 62 considered that remaining NK cells inhibited homing and maintenance of human cells. To overcome 63 the effects of NK cells, Scid/Beige mice were established by crossbreeding SCID mice and Beige mice. 64 The taking rate of human tumor cells are increased in Scid/Beige mice compared with Scid mice as 65 expected. However, the engraft rate of human HSCs are not clearly increased [12].

66 2.3. NOD/Scid mice

67 In 1980, Non-obese diabetic (NOD) mice were discovered by Makino S, which develop diabetes 68 by the infiltration of T lymphocytes into the pancreatic islets [13]. It is also showed that NOD mice 69 multiple immune abnormalities including loss of complement, impaired NK, macrophage and 70 dendritic cell function [14]. NOD/Scid mice were established by crossing NOD and Scid mice, which 71 do not develop diabetes due to loss of functional T lymphocytes. NOD/Scid mice were shown to have 72 multiple defects in innate and adaptive immunity, which provided an excellent recipient of human 73 hematopoietic stem cell transplantation [15] and human solid tumors. Several trials were performed 74 to suppress the residual NK activity using anti-IL-2 receptor antibody or asialoGM1 or cross with β^2 75 microgloblin or perforin deficient mice, and improved the efficacy of transplantation. Finally 76 NOD/Scid mice with complete loss of NK cells were established by crossing NOD/Scid mice with IL-77 2 receptor deficient (NOD/Scid/IL2Rynul:NOG[16], NOD/Scid/IL2Rynul:NSG[17])or Jak3 deficient 78 mice (NOD/Scid/Jak 3^{null} :NOJ[18])(Table 1). Recently, Signal regulatory protein alpha (SIRP α)-CD47 79 signaling, so called "Don't eat me" signal was shown to play an important role in tumor and graft 80 rejection by macrophages[19], and polymorphism of SIRP α in the NOD mice strain contributes the 81 efficient human cell engraftment into NOD strain (Figure 1) [20,21]. BALB/c mice strain also have 82 SIRP α polymorphism with affinity to human CD47, and in fact, BALB/c strain immunocompromised 83 mice such as BALB/c Rag-2^{null}/IL2Rγ^{null}[22] and Rag-2^{null}/Jak3^{null} mice[23] are also useful recipient mice 84 for human cell and tissue transplantation[24,25]. Other genetic background of the mice such as 85 C57/BL6 mice were shown to have lower efficacy to accepting human normal and malignant cells 86 [23,26]. Since SCID mutation has several disadvantages such as high radiation and drug sensitivity 87 and leakage of T lymphocytes, Rag-1/Rag-2 knock out mice are also using for eliminating mature 88 lymphocytes (Table 2) [22,27].

116 **3. Establishment of Nude/Hairless immunocompromised mice**

117 Although more combined immunocompromised mice have been developed, Nude mice were 118 still used in human tumor engraftment due to the benefit of hairless phenotype. It is easy to detect 119 subcutaneous tumors and its application for in vivo imaging. We crossed Nude mice with Rag-2^{null} 120 and Jak3null mice with a BALB/c background and established BALB/c Nude Rag-2/Jak3 double 121 deficient (Nude RJ) mice[28,29]. Nude RJ mice has no B and T lymphocytes with Rag-2 deficiency, no 122 NK cells with Jak3 deficiency, and had "Don't eat me signal" with BALB/c background. Nude RJ mice 123 keep the advantages of no coat hair and higher immunocompromised level than Nude mice, and 124 consequently, optimized for *in vivo* imaging (Figure 2). The mice expressing fluorescent protein are 125 powerful tool in cancer research to visualize the tumor-host interaction[30], and several types of 126 fluorescence expressing immunocompromised mice are established and utilized for human cancer 127 research [31-33]. These mice are useful to analyze the relation with human tumor and tumor 128 microenvironment such as tumor vessel, tumor associated macrophages (TAM) and cancer 129 associated fibroblasts (CAF) [34]. There exists another type of no coat hair mice, hairless mice, without 130 major immunodeficiency [35,36]. SCID hairless (SHO) mice (Charles River) and Hairless NOD/Scid 131 mice (Envigo) were established backcrossing with Hairless mice and also using in vivo imaging (Table

132 3) [37,38]. However, expected engraftment efficiency is lower than NK deficient strains.

144 3. Establishment of PDX model using various immunocompromised mice

145 PDX models are generated with engraftment of patient tumor samples into 146 immunocompromised mice (Figure 4). An important advantage of PDX model is that they retain key 147 characteristics of patient's tumor, such as gene expression profile, heterogeneity of tumor cells. 148 Currently, PDX models are most clinically relevant in vivo cancer models, and represent highly 149 predictive drug response platform [39] US National Cancer Institute (NCI) decided to retire NCI-60, 150 a panel of 60 human cell lines from its drug screening, and use PDX model [3]. PDX is now expected 151 as the most useful "Avatars" for individualized medicine. The duration of first tumor growth in mice 152 differs and it usually takes a few months to observe the tumor growth (F0). The duration of tumor 153 growth is going to stably approximately 2 months with the serial transplantation [40]. PDX samples 154 can be stored with patient's clinical data, gene-expression patterns, mutational status, drug 155 responsiveness and pathological analysis to make PDX library.

156

157 158

58 Figure 4. Patient-derived xenograft (PDX) model

159 Nude mice have been used to generate PDX models with reasonable efficacy and continuously 160 used as standard recipient (Table 5). In fact, the engraft efficiency of gastrointestinal tumors are 161 relatively high, however; establishment of hematological tumor PDX is almost impossible with Nude 162 mice. Introduction of Scid and NOD/Scid mice increased the success ratio [41]. As NOD/Scid mice is 163 known to has relatively short life span and develop thymoma [15], recipient of PDX is now shifting 164 to more immunocompetent NOG/NSG mice [42-44]. Success ratio of PDX varies between tumor 165 origin, aggressiveness, relapsed or not, primary tumor or metastatic tumor. Gastrointestinal cancers 166 such as colon and pancreatic cancer tends to high engraft ratio compared with hematological 167 malignancies. Orthotropic or renal capsule engraftment is needed some tumors [24]. Human 168 hormone replacement supports hormone dependent tumors such as breast and prostate cancers 169 [45,46].

170 4. Generation of PDX derived cell lines

Tumor cell line can be generated from PDX tissue sample [40,47,48]. It is hard to establish tumor cell lines from primary tissue, because fibroblasts are predominantly developed during in vitro culture in most of the cases. Human fibroblasts are replaced to murine fibroblasts in the PDX tissue, and these fibroblasts are regenerated during *in vitro* culture. It is of interest that male derived tumor cells keep Y chromosome in PDX tissues but lose it during developing cell lines, indicating that at least one more hit is needed to establish cell lined from PDX. PDX derived tumor cell lines can use for the drug screening as they still keep the character of primary tumors.

178

such as whole exome sequencing (WES), RNA sequence (RNA-seq), and copy number alteration (CAN) analysis.
 Tumor cells are also preserved in liquid nitrogen tank. Tumor cells are further transplanted into immunocompetent mice (7), and expanded tumor xenografts (F2-F3) are used for drug screening, validation of biomarkers, characterization of tumor, etc.

212 **5.** Perspective

213 PDX models have emerged as important tools for cancer research with the promise of enabling 214 a more personalized approach together with gene-expression and drug sensitivity profiles. However, 215 PDX requires long time for establishment (several months to 2 years) and success rate is not 100% 216 (10-90%). So it is difficult to restore the data for the patient of tumor source. Therefore, many 217 institutions and organizations are focus on creating large stock of PDXs and PDX libraries. European 218 institutions established EurOPDX, a consortium to store PDXs and have already accumulated more 219 than 1,500 samples in a PDX bank [66,67]. Jackson Laboratory provides more than 450 samples to 220 researchers [43]. Mega Pharmacies are also establishing their own PDX libraries, and Novartis 221 recently published data on drug screening using 1,000 PDXs [68]. These PDX banks are very useful 222 source for precision cancer medicine. As current source of PDX is biased in USA and European 223 countries and common cancers, it is necessary to establish PDX in Asian countries and rare cancers.

224 Developments of xenograft technology and highly immunocompromised mice such as NSG 225 mice enable us for broadening the application of the PDX platform. However, we need more effort to 226 establish clinically relevant PDX. For example, Humanized mice with PDX are expected to function

as a novel platform for examining immunotherapy [69]. Several attempts have been made to establish

- 228 more humanized microenvironments in immunocompromised mice [70].
