Abstract

Background: Qazvin province has suffered a lot of natural disasters (earthquakes) for a long time. so, the establishment of the first industrial city in Iran, has always been a source of concern. One of these problems is the possibility of chlorine gas leaking from the chlorination system of drinking water and treatment plant the existing ones are on the health of the inhabitants of this region.

Material and method: This analytical study was carried out in Novorossiysk district of Alborz in December 2012. Initially, chlorine gas leakage scenarios from these facilities were simulated by ALOHA and WISER software, and then using the Emergency Level System, according to the CCPS Consultative Center's Chemical Process Safety Advice, the Emergency Response Program was presented.

Results: ALOHA software, in comparison with WISER software, has more precision to identify and address the consequences of chlorine gas leakage hazards and according to the simulation of this software in the event of a leak from the well and water resources unit at 8240 m from the area and at night 7520 meters will be affected. Due to the speed of delivering results through the WISER software, this software can be used at times when the operating speed is considered (incident time).

Conclusion: According to the CCPS model, the emergency conditions were classified at levels 3 and 4, therefore, the relevant crisis management agencies (Qazvin Crisis Management Committee, Alborz City Health Center, Red Crescent and Firefighting Authority) should provide training maneuvers At Alborz city level, and informing people of cities and industrial companies, many efforts have been made to reduce human and environmental damage in case of possible leakage.

Keywords: Chlorine Gas Leakage, ALOHA, WISER, CCP, Cancer

Introduction

Qazvin province was the capital of Iran during the reign of Shah Tahmasb I and was very prosperous politically, religiously and commercially [1]. The occurrence of very severe earthquakes during the capital of Qazvin was one of the important factors in transferring the capital from Qazvin to Isfahan [2-4]. Regardless, the establishment of industrial units began in the Safavid era, and over time it went through stages of growth. Alborz industrial city started in 1968 as the first industrial city of Iran [5]. According to the Ministry of Industry, the Alborz Industrial City was established in 1347 to implement decentralization policies for industrial workshops in Tehran and to create new industrial hubs outside the Greater Tehran area [6]. And erected on 900 hectares of land, 140 kilometers northwest of Tehran and 15 kilometers southeast of Qazvin. 550 acres were allocated to the east, industrial areas (Which holds about 450 manufacturing and industrial units), 112 acres of commercial areas (80 hectares to residential areas and 32 hectares to commercial areas, including 394 business units - workshop, more than 603 Commercial - Neighborhood units) and the rest of the land to public roads and facilities. The population of Alborz city according to the 2011 census was 203276 people, which is very important for water supply, industrial and household use. The city has two water drainage units (Wells and Water Resources Unit, which is responsible for supplying potable water in the northwest including telemetric installations for continuous and online control of water pressure and total water consumption, a metallic air source of 2000 cubic meters with a height of 42 meters), the largest refinery in the Middle East, with a capacity of up to 90,000 cubic meters, which is responsible for water supply for agriculture and is located in the southwest of the city [7]. Exposure to chlorine gas at a concentration of 14-21 ppm for half to one hour is dangerous and a concentration of 100 ppm cannot be tolerated for more than one minute [8]. In fact, it is toxic but not carcinogenic [9, 10]. But Rook discovered that the combination of chlorine with organic compounds in drinking water produced halogenated organic compounds-chloroform [11]. That is a carcinogen [12]. Also Morris suggest a positive association between consumption of chlorination by-products in drinking water and bladder and rectal cancer in humans [13]. Under normal conditions, if 10 tons of chlorine is released into the air, it will produce a concentration of 140 ppm within 2 km of the source and a concentration of about 5 ppm within 5 km. Due to the use of chlorine in urban areas and population density in large cities, the depth of the disaster is clearly evident [14]. Chlorine gas leak from Astara's 50-tonne cylinder kills 40 and injures 200, and the accident of chlorine gas leak at Tehran Water Treatment Plant in December 2001 resulted in the death of 2 people and the injury of 50 people [15]. According to official statistics, production, transportation, consumption and storage of chlorine takes 52 lives daily. Following is a list of a number of chlorine gas events in Iran and around the world.

Table-1: Chlorine gas leakage events in Iran

Year	Month	City	Cause	Consequences
2004	October	Iron scrap market, Tehran	Chlorine leak from used capsule	2 injured
2011	August	Tehran	Chlorine gas leaks in a pool	14 injured
2012	January	Mashhad	Chlorine gas leaks in a pool	30 schoolgirls poisoned
2012	February	Hunan Pool, Sarasiab St, Tehran	Chlorine gas leaks from a capsule	4 persons with respiratory problems
2012	July	Elahieh Hotel, Qazvin	Chlorine gas leaks from a capsule	190 hospitalized

2012	September	Paksho Company, Alborz Industrial City, Qazvin	Combining Sodium hypochlorite with hydrochloric acid and creating chlorine gas	7 persons with acute respiratory problems
2012	December	A swimming pool, Tabriz	Chlorine gas leaks from a capsule	9 persons with respiratory problems
2013	December	Eghbaleh, Qazvin	Chlorine gas leaks from a capsule	6 persons with acute respiratory problems
2015	September	Chanan Castle Village, Khuzestan	Deliberate release of 100 Kg capsules by thieves	100 poisoned
2017	August	Dezful, Khuzestan	Chlorine gas leaks from a 700 Kg capsule	475 injured

Table-1: Chlorine gas leakage events in the world

Date	Country	Cause	Consequence
April 30, 1974	Yukaiichi, Japan	Chlorine leak in transit	521 killed
February 22, 1978	Youngston, USA	Chlorine leak in rail transport	8 killed, 138 injured
August 4, 1981	Mexico	Accident during chlorine road transport	28 killed, 1000 injured and 5000 drain
July 7, 1987	The former Soviet Union	Accident during chlorine transport	200 injured
January 17, 1990	Germany	Release of chlorine from the tanker	More than 182 injured
April, 1994	India	Accident during transport	1 killed, 150 injured
January, 1997	Pakistan	Accident during transport	22 killed, 900 injured and 1000 drain
April 16, 2004	Chin	Chlorine leakage from chlorination station	9 killed and evacuated people up to 3 km radius
April 30, 2004	Chin	Chlorine leak	282 Outpatient Injury, 6 Injury
April 11, 1996	Montana, USA	Chlorine leak	350 injured
March 31, 2005	Chin	Take the tanker off the rails	27 killed, 285 injured
April 12, 2005	Chin	Chlorine leak	88 injured
January 6, 2005	USA	Take the tanker off the rails	8 killed, 260 injured
January 13, 2005	North Carolina, USA	Take the tanker off the rails	9 killed
April 21, 2006	Chin	Chlorine leak	22 injured
July 10, 2006	Chin	Chlorine leak	164 injured
September 21, 2007	Chin	Chlorine leak	62 injured

In a study by Ramabraham and Swaminathan (2000) at a chlorine gas storage facility, after studying the process risks, a general template for an emergency response program was presented that was useful, but general, and Emergency levels for different release scenarios were not specified [16]. Adel et al. (2007) identified the most important factors in the occurrence of chlorine leakage in drinking water chlorination stations using Fault Tree Analysis (FTA) technique, and the most important causes of the chlorine leakage were, low skill level of staff (due to lack of appropriate training courses for relevant personnel), high workload on staff, lack of integrated guidelines and regulations in the chlorination stations, design flaws and the probability of an happening accident 21 times a year (That was a relatively high figure). By modifying the basic concepts or designing the stations, the probability of an accident decreases dramatically on a

standard basis [15]. Tsang et al. (2008) examined the different stages of a chlorine gas emergency response program in process plants in Taiwan, but did not use any process risk assessment methods and did not specify release scenarios, also the radius of damage was not specified when released into the environment. In this study, IDLH of chlorine gas considered PPM 30 (Immediately Dangerous to Life or Health Concentration)[17]. Some studies have measured the consequences of environmental toxicity with the criteria of TLV-TWA, ERPG, LD50, TLV-STEL, PROBIT [18-23]. Mahoney et al. (2008) presented a model for identifying emergency response areas as hot, warm and cold areas with ALOHA (Areal Location of Hazardous Atmospheres) software around the toxic gas emission range based on the Acute Exposure Guideline Levels (AGLEs), but in the study They did not mention the duties of the various groups when emitting toxic gases [24]. Thus, given that a large number of major industrial events in the last century have been related to the release of toxic chlorine gas into the environment [25, 26]. People at risk of exposure can include the workers near the leak site and community members who residing adjacent to industrial areas [27]. The main purpose of this study was to describe possible scenarios of chlorine gas leakage from the drainage unit of wells and water resources and treatment plant in Alborz city and its possible effects on urban and industrial areas.

Materials and methods

This study was carried out in December, 2016, in the drainage unit of wells and water resources of Alborz city. In the water drainage unit, there are two 800-kg chlorine gas cylinders, which are transported in a supine position and the outputs of these two cylinders are connected to the drainage circuit cylinder. The cylinder was perpendicular to collect the chlorine impurities below the cylinder and to send chlorine gas from the top for chlorination, and the cylinders were kept in a 2-by-2-meter room. Room temperature in summer is ambient temperature and in winter use of heating devices to prevent freezing of chlorine gas and an average of 15 days an 800-kg cylinder is used. Due to the importance of chlorine gas in this study, ALOHA and WISER software were used to simulate the potential of chlorine gas leakage. Both of this software are widely used in crisis management and emergency response. Today, many models have been developed for modeling gas emissions and they are developing. These models are presented in software packages using mathematical models, each of them has advantages and disadvantages, the most important of which are ALOHA, PHAST, HGSYSTEM, DEGADIS – SLAB [18, 19, 22, 28-31]. ALOHA software has various features including material database, prediction of concentration at a given location and moment, fire radiation and explosion wave charts, wind speed, geographical conditions, surface roughness, distance and modeling time [32]. It is a powerful computer software that is used to calculate the probable outcome of an accident [33]. WISER (Wireless Information System For Emergency Responders) software is used for hazardous chemical accidents and contains extensive information on hazardous substances, Includes: Identification of 5236 chemicals and 438 matter base on physical and chemical properties, Guidelines for material identification, Physical characteristics, Medical information and Material safety data sheet, also It is generally a reference for rapid modeling in the early minutes of major events and is used in both Android and Windows [34]. The software was used in the explosion of the Canadian Quebec freight train, which estimated the effects of the blast on the affected area. The train was carrying crude oil from North Dakota, that departed from the railroad on July 6, 2013 in Lak Magentic, 250

kilometers east of Montreal. this fatal accident killed 47 people and caused hundreds of millions of dollars in damage. This is the biggest rail accident in the last two decades [35]. the emergency response program was developed according to the process safety management system, which has a great importance and advantage in the process industries [36, 37]. In this system, emergency levels were defined as recommended by Center for Chemical Process Safety (CCPS). According to the severity of the accident, the extent of the pollution spread and the exposed population in the event, emergency actions were divided into four categories: Emergency Level 1: When hazardous substances exist or likely exist, but there is no leakage, spillage, fire or explosion, and it is not expected to occur. Emergency Level 2: When there are no serious health effects, but release or fires may be diagnosed by people working due to odors or clouds, and the surrounding population may be paying attention and asking questions. Emergency Level 3: When release or potential release is identified as a threat to the health of the surrounding community and is likely to be caused by control measures. At this level, emergency responders will be alerted to take action if necessary. If control is lost, release can become an emergency situation in society, or if the control is successful, the level of emergency can be reduced to level 2. Emergency Level 4: When the happened release can cause adverse effects on the community living around of the industrial area, at this level all emergency responders in the city are aware of the accident and take appropriate action. At this level, appropriate response measures are spread to the surrounding community[38].

Results

As mentioned, Alborz Industrial City is bounded from the northwest by the drainage unit of wells and water resources and from the southwest by the drainage unit of the sewage treatment plant. Given that the annual wind direction of May wind in Qazvin province from the north and northwest and the secret wind from the south and southeast (wind percentage 7.12 and speed of 4 m/s is more intense from mid-spring to late summer) [39]. in the two-wind mentioned above, there is more emphasis on the expression of scenarios.

The worst-case scenario provided by WISER software is a leakage from a treatment plant (Figure 1) or wells and water resources (Figure 2), and the direction of the wind to the south and north respectively and the possibility of leakage at night. The following two figure are specified, the Isolate 500 and the Affected Areas are 7900 meters, which confirms the importance of developing and implementing an emergency management plan for all Alborz residents (including Alvand and Nosrat Abad).

Figure 1: Simulation of chlorine gas leakage from the treatment plant using WISER software

Figure 2 - Simulation of chlorine gas leakage from wells and water resources using WISER software

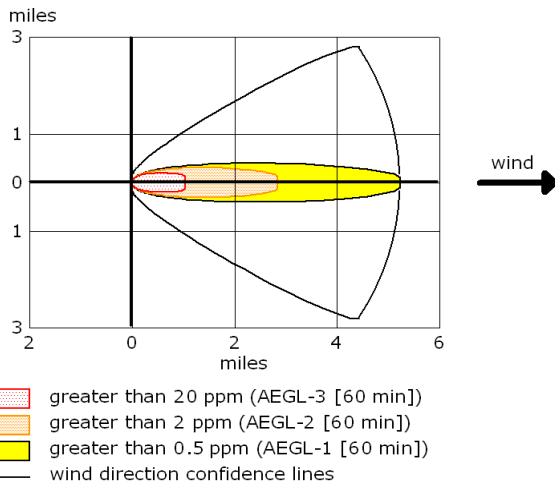

Figure 3: Simulation of high daily chlorine gas leakage from wells and water resources using ALOHA software

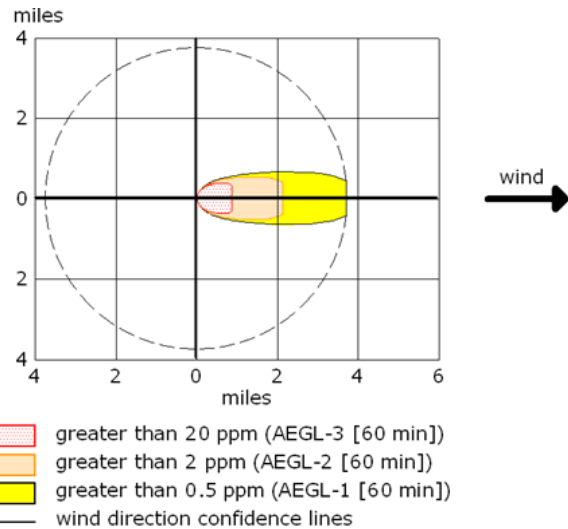

Figure 4: Simulation of high chlorine leakage at night from the treatment plant using ALOHA software

Table 3: Chlorine gas leak simulation with ALOHA and WISER software

Leakage location	Leak age	Time	wind direction	ALOHA			WISER		involved Areas	
				Hot (meter)	Warm (meter)	Cold (meter)	Isolate d area (meter)	Effecti ve area (meter)		
1	Wells and Water Resources	Much	Day	North to South	1600	4800	8000	500	3000	Alborz Industrial City
2	Wells and Water Resources	Low	Day	North to South	1280	4000	7200	60	400	Companies close to chlorination
3	Wells and Water Resources	Much	Night	North to South	1600	4480	7520	500	7900	Alborz city
4	Wells and Water Resources	Low	Night	North to South	1120	3680	6880	60	1500	Near Industrial City Square 2
5	Wells and Water Resources	Much	Day	South to North	1600	4800	8000	500	3000	At the beginning of the industrial city road
6	Wells and Water Resources	Low	Day	South to North	1280	4000	7200	60	400	Places near the drainage unit

7	Wells and Water Resources	Much	Night	South to North	1600	4480	7520	500	7900	Municipality Residential Areas
8	Wells and Water Resources	Low	Night	South to North	1120	3680	6880	60	1500	At the beginning of the industrial city road
9	treatment plant	Much	Day	North to South	1440	3520	6720	500	3000	Alborz Industrial City
10	treatment plant	Low	Day	North to South	800	2400	4560	60	400	Places near the drainage unit
11	treatment plant	Much	Night	North to South	1440	3040	5440	500	7900	Alborz city
12	treatment plant	Low	Night	North to South	800	2720	4800	60	1500	Places near Industrial Square 2
13	treatment plant	Much	Day	South to North	1440	3520	6720	500	3000	At the beginning of the industrial city road
14	treatment plant	Low	Day	South to North	800	2400	4560	60	400	Places near the drainage unit
15	treatment plant	Much	Night	South to North	1440	3040	5440	500	7900	Municipality Residential Areas
16	treatment plant	Low	Night	South to North	800	2720	4800	60	1500	Nearby Places industrial city road

Discussion and conclusion

In general, due to the confinement of Alborz city to both chlorination units and the monsoon winds that cause the possible transfer of chlorine gas leakage to residential areas (Nosrat Abad and Kemalabad and Alborz Industrial City). Emergency situations can be classified into levels 3 and 4 according to the CCPS model. Therefore, the relevant crisis management organizations (Qazvin Governorate Crisis Management Committee, Alborz Health Center, Red Crescent and Fire Department) should make great efforts to conduct educational maneuvers at Alborz city level and to inform the people of industrial cities and companies to reduce the amount of human and environmental damage if the leak occurs. The results of the Shahidi and Motevalian study showed that chlorine gas poisoning induces mitosis of murine white blood cells and in fact can be considered as an effective factor in the proliferation of white blood cells. In other words, although chlorine cannot be categorically identified as a carcinogen, it can at least be regarded as a mitogen, but further research is needed to prove it carcinogenic[40]. In this study, it was found that ALOHA software is more accurate than WISER software for identifying and presenting the consequences of chlorine gas leakage on residential and industrial areas of Alborz city. and by simulating this software, the leakage from the wells and water units will be affected at 8240 meters per day and 7520 meters at night, Therefore, it is recommended to use this software to provide emergency response program and training exercises, but given that in emergencies situations, timing of accidents, speed of operation, and time savings are crucial and very important, Therefore WISER software is able to instantly identify danger areas by selecting chlorine gas, wind direction and leakage (low or high), so that control measures can be taken in critical situations.

Recommendation

Considering that the most important part of crisis management is providing strategies and opinions when establishing and building high-risk units, Therefore, it is recommended to use the aforementioned software to identify safe areas before construction of chlorination units.

Unfortunately, in recent years, public construction has expanded to the areas surrounding the wells and water resources drainage unit (so called municipal lands), it is suggested that with the supervision of relevant units with Qazvin Governance Crisis Management, First, identify safe locations and then the permit is issued by the municipality. Residents of these areas are also at serious risk if chlorine gas leaks from wells and water and blowing secret wind.

As mentioned, in the area of crisis management, the most important principle is risk prevention. It is hoped that trustee organizations will step in with more vigor and oversight in this area and avoid the traditional thinking of curing the event at the time of the incident.

It is recommended to be used in future studies before identifying high-risk units such as chlorination, using various software to identify safe locations for residential, commercial and industrial construction, and administrative instructions are communicated to the trustee units, and its implementation monitored.

Acknowledgment

To all the dear colleagues who assisted us in the preparation of this study, We have the ultimate gratitude.
