35

36 Abstract

37 **Aim:** The purpose of this examination is determining predictors to oral health behaviors predict in Iranian
38 students in district 1 Tehran based on the health belief model with added commitment to plan construct.

39 **Methods:** This cross-sectional study were randomly selected conducted on 351 eligible four grade female
40 students in the first district of Tehran, Iran in 2017. The random Multi-stage random cluster sampling
41 method was used to recruit students. The inclusion criteria were being graded, four female students (aged
42 9-11 years), or education at the fourth grade of one of the elementary schools studied in the first district of
43 Tehran and, The health of the student from a physical and psychological of view. Logistic regression
44 analysis was used to identify the variables that predict oral health behaviors. To assess the predictors of
45 oral health behaviors, all the expanded Health Belief Model constructs with the construct of
46 “Commitment to Plan of Action” from “Health Promotion Model were examined as risk factors to see if
47 they influence on the probability of brushing behavior and dental floss behavior occurrence and were
48 interpreted through odds ratio (OR). SPSS version 19 was used to analyze the data.

49 **Results:** Totally 308 four grade female students with mean age of 9.32 ± 0.81 years old took part in the
50 study. The total 31.8% of the students reported that they were brushing behavior less than twice a day and
51 55.2% students claimed, use of dental floss behavior once a week or less than once a day. The results
52 indicated that perceived self-efficacy (OR=1.46, 95% CI=0.57-3.78, $P<0.001$), Commitment to plan
53 (OR=1.13, 95% CI=1.04-1.23, $P<0.001$) and Cues to action (OR=1.42, 95% CI=1.14–1.76, $P=0.002$)
54 were the significant predicting variables which is the key factor of brushing twice a day, and use of dental
55 floss once a day or more (OR=1.02, 95% CI=0.23-3.53, $P=0.003$).

56 **Conclusion:** This study has shown the effectiveness of the health belief model with added commitment to
57 plan construct to predict oral health behavior in female students. So, it seems that the model as a
58 framework for designing training programs to improve students to improve oral health behavior can be
59 used.

60 **Key words:** Oral Health; Students, Medical, Behavior, Iran.

61

62 **Introduction**

63 Oral disorders are the most common health problems. Studies have shown that one of the
64 commonest problems of early life is dental caries and oral diseases. Oral health is a part of the
65 public health and essential to enhancing the quality of life¹. Primarily based on the precept that
66 prevention and training are the satisfactory manners of promoting oral health collectively, that
67 extra prematurely preventive measures and interruption on disease evolution are established
68 more effective might be the results².

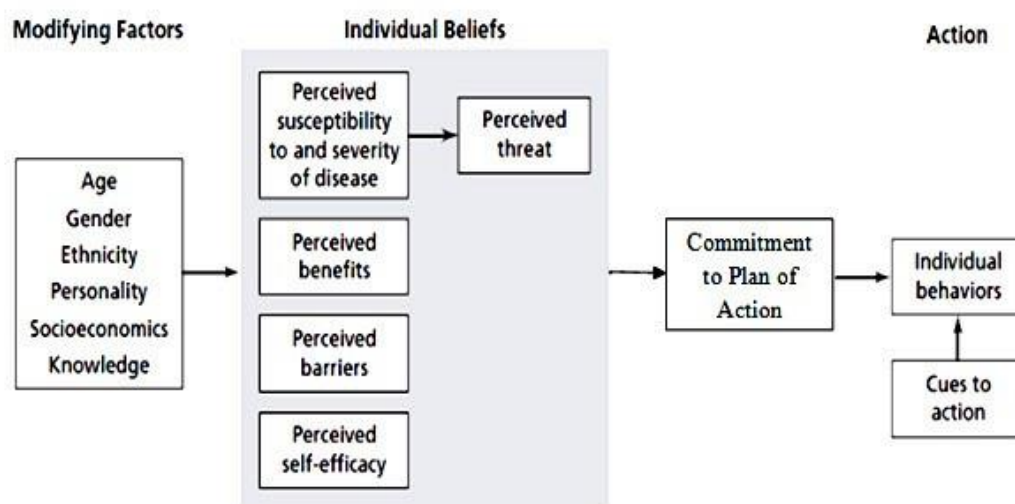

69 Distribution and severity of oral conditions vary in different components of the world and this is
70 also real for specific geographic conditions within the equal country or area³. According to a
71 countrywide oral health survey performed in 2012, indicated a high level of carries inside the
72 primary dentition and the mean DMFT index become pronounced with 5.16/0.38 in 6-year-old
73 children⁴.

74 Behavior elements and factors are received in early childhood and there is a strong mother or
75 care. There is the fact that habits are at this age and caries in the first teeth². Brushing and
76 flossing are the very best methods to reduce the incidence of plaque⁵.

77 In addition, health education is considered a critical method for health promotion, now not best
78 by the impact and voluntary wonderful adjustments within the individual's way of life and health
79 habits; additionally, it improves familiar and community behavior, producing political behaviors
80 that allow the development of new strategies to promote health and enhance the quality of
81 lifestyles of the populace^{2, 6}. The implementation and effectiveness of educational preventive
82 programs have become relevant because of the interception of risk factors for oral diseases,
83 knowledge acquisition and consequently behavioral changes⁶.

84 In health education; the use of models and theories of health behavior to interventions is
85 recommended because they can cause powerful health education programs. In fact, the models

86 provide a framework for expertise on how people analyze and the way they behave and why
 87 humans behave as they offer⁷. The Health Belief model method is a comprehensive model that
 88 can be used for organizing educations. The HBM is a number of the first models which were
 89 advanced for regulating health-related behaviors⁸. On this version there are specific patterns of
 90 social-cognitive predictors can also appear (Figure 1) the construct of “Commitment to Plan of
 91 Action” from “Health Promotion Model Added to HBM model.

92
 93 **Figure 1.** Flow Diagram of the expanded Health Belief model with the construct of “Commitment to Plan of
 94 Action” from “Health Promotion Model.
 95

96 The model assumes that different factors, consisting of the perceived severity of health trouble,
 97 perceived benefits, and perceived barriers preventing people from assignment preventive
 98 behaviors, affect health related beliefs and behaviors⁹. The purpose of this examination is
 99 determining predictors to oral health behaviors example teeth brushing frequency, dental floss frequency
 100 and in Iranian students in district 1 Tehran based on the health belief model with added commitment to
 101 plan construct.

102

103 **Materials and methods**

104 Study design and participants

105 The study was cross-sectional, which was conducted on the grade four female students (9-11
106 years) of schools in the first district of Tehran on April 21, 2017, for 2 months. To obtain
107 samples from among the 33,179 female students (grade four) studying in this Urban-rural, a
108 Multi-stage random cluster sampling method was used.

109 In the first stage, out of 162 schools (145 urban schools and 17 rural schools), 10 schools [Urban
110 schools (N=6) and Rural schools (N=4)] were randomly selected.

111 In the second stage, From 351 students with it were random Based on the share of the population
112 from each school and the number of schools and students in each school after declines 43
113 students, Assessed for eligibility (n=308) (Table 1).

114 The inclusion criteria were being graded, four female students (aged 9-11 years), or Education at
115 the fourth grade of one of the elementary schools studied in the first district of Tehran and, The
116 health of the student from a physical and psychological point of view and the exclusion criterion
117 was Student or parent's disagreement with the student company in the study and, the student
118 determines the confrontation with their company in the study, the selected students were asked to
119 respond to the study questionnaire.

120 The researcher was present while completing the questionnaire to help the students. The students
121 were defined in the event that they to answer truly, this may assist the researchers to acquire the
122 right information and improve knowledge (Figure 2).

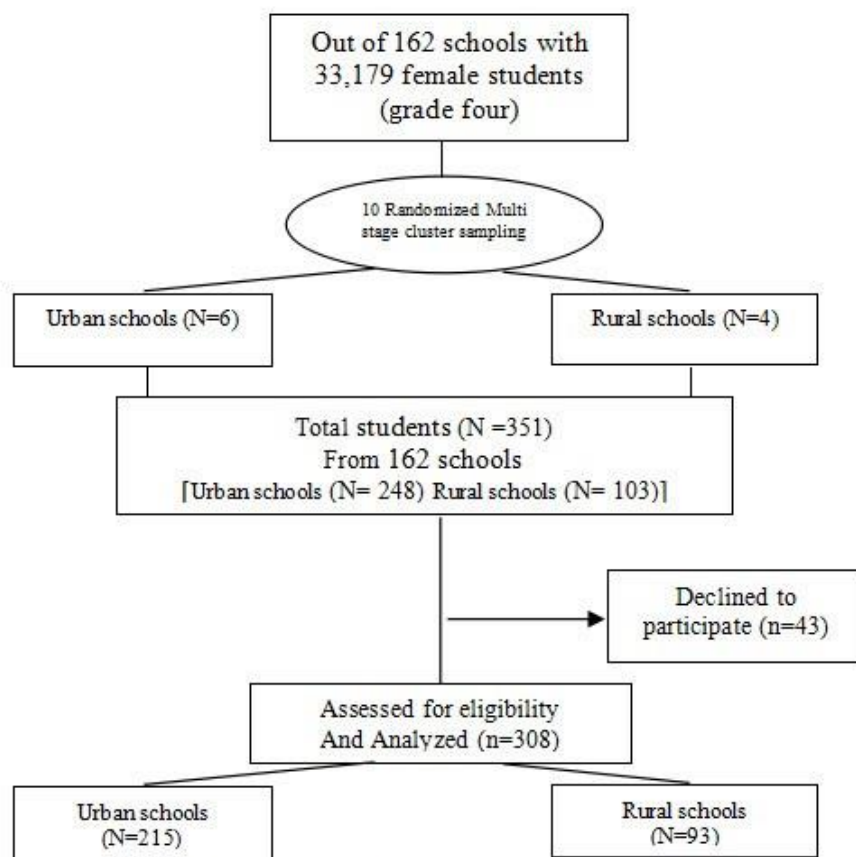

123 All ethical issues were considered in this study. After explaining the aims and procedures of the
124 study, all participants were satisfied to be studied and voluntarily signed the written consent
125 form. Research Ethics Committee of Shahid Beheshti University approved the study on 2016.3.5
126 (ID IR.SBMU.RETECH.REC.1396.625). Data were entered into the SPSS software version 19

127 and analyzed through Logistic regression analysis. $P < 0.05$ was thought-out statistically
128 substantial.

129 Based on the existed reference the sample size was estimated on the basis of ten individuals for
130 each item¹⁰. Therefore for a 31 item questionnaire a sample size of $31 \times 10 = 310$ were
131 calculated. However, for greater accuracy, the sample size was increased to 351 individuals.

132 To assess the predictors of SE, all the oral health behaviors, all the expanded Health Belief
133 Model constructs with the construct of “Commitment to Plan of Action” from “Health Promotion
134 Model constructs (Table 2,3) were examined as risk factors which could influence the probability
135 of occurrence SE and were interpreted through odds ratio (OR). The odds ratio was used to
136 determine whether particular exposures like the above constructs could be risk factors for the
137 occurrence of the outcome like rushing behavior and dental floss behavior. Odds ratios are used
138 to predict risk factors in case-control, cross-sectional and cohort study designs¹¹. SPSS version
139 19 was used to analyze the data.

140

142

143

Figure 2. Flow diagram of student's recruitment.

144 Results

145 Totally, 308 four grade female students in the first district of Tehran took part in the study. The
 146 mean age of the subjects was 9.32 ± 0.81 years. The demographic variables of the study
 147 population are shown in Table 1, 2. About 31.8% of the students ($n =98$) reported that they were
 148 brushing behavior less than twice a day, and 170 students (55.2%) reported that they used once a
 149 week or after using dental floss behavior or less than once a day. While 210 students (68.2%)
 150 reported that they brush behavior at least two twice a day, 138 students (44.8%) reported that
 151 they were using dental floss behavior at least once a day. The results indicated that perceived
 152 self-efficacy (OR=1.46, 95% CI=0.57-3.78, $P<0.001$), Commitment to plan (OR=1.13, 95%
 153 CI=1.04-1.23, $P<0.001$) and Cues to action (OR=1.42, 95% CI=1.14–1.76, $P=0.002$) were the

154 significant predicting variables which is the key factor of brushing twice a day, and use of dental
 155 floss once a day or more (OR=1.02, 95% CI=0.23-3.53, P=0.003).

226 OR = odds ratio, CI = confidence interval

227
228

Second stage

229 Using a logistic model for testing, the effect of six structures of HBM and demographic variables
230 having a significant relationship with oral health behaviors. Tables3, 4show the data used in the

231 model. In order to find out the relationship between oral health behavior and independent
 232 variables, simple and multiple logistic regression analyses were carried out with five-six
 233 structures of HBM and demographic variables that were significant according to Tables 3,
 234 Mother's education (P =0.005), income (P =0.007), self efficacy, Commitment to plan (P
 235 <0.001) and Cues to action (P =0.003) predicted the students' behavior of Dental floss at least
 236 twice a day.

237 However, after adjustment, only perceived self-efficacy, Commitment to plan, Cues to action
 238 remained significant, so that one unit increase in perceived self efficacy increased the possibility
 239 of teeth Brushing behavior at least twice a day by 1.42 times, Commitment to plan by 1.02 times
 240 Cues to action by times.

241 **Table4.** Factors predicting use dental floss behavior at least once a day among of students

Dental floss behavior	B	Simple OR (95% CI)	P-Value	B	Multiple OR (95% CI)	P-Value
Mother's job			0.006			0.012
Father's educational level			0.004			0.113
Primary	0.18	1.20(0.54-2.70)	0.61	1.19	0.78(0.37-1.69)	0.23
High school	0.47	1.60(0.92-2.78)	0.01	0.28	1.36(0.47-2.68)	0.01
Higher educational	2.61	0.74(0.33-1.65)	0.03	0.52	1.65(0.97-2.83)	0.01
Income			0.007			0.104
Low	-0.56	0.56(0.18-1.72)	0.31	0.45	1.31(0.83-2.43)	0.28
Appropriate	-0.034	0.96(0.31-3.01)	0.95	0.20	1.15(0.55-2.66)	0.23
Well	0.13	1.14(0.35-3.65)	0.81	0.21	1.12(0.35-2.53)	0.01
Self-efficacy	0.53	1.78(0.66-4.74)	<0.001	0.36	1.30(0.99-2.34)	0.016
Commitment to plan	0.18	1.13(1.043-1.23)	<0.001	0.15	0.89(0.38-1.54)	0.21
Cues to action	0.16	1.02(0.23-3.53)	0.003	0.14	1.02(0.89-3.44)	0.002

242 OR = odds ratio, CI = confidence interval

243
 244 The results showed that the students' use of dental floss behavior was significantly related to the
 245 mother's job (P = 0.006), Father's educational level (P = 0.004), income (P =0.007) perceived
 246 self efficacy (P <0.001), Commitment to plan (P <0.001), and Cues to action (P = 0.003). When
 247 they were separately entered into the model (Table 4) Nevertheless, after adjustment, mother's
 248 job (P = 0.012) and self efficacy (P =0.016) were found to be significantly related to the use of
 249 dental floss once a day or more. The increase of perceived self efficacy by one unit, the

250 possibility of using dental floss at least once a day will increase by 1.30 times (OR = 1.30, 95%
251 CI = 0.99-2.34, P = 0.016).

252 **Discussion**

253 The current survey was designed to investigate the predictors to oral health behaviors are
254 expecting in Iranian students in district 1 Tehran based on the health belief model with added
255 Commitment to plan construct Consistent with this examine findings, other research has
256 mentioned a significant relationship between the education level of mother and father As
257 Aggarwal study¹² Contrary to the Pourhaji study, there was no significant relationship between
258 education level and oral health behaviors the two groups ¹, a significant relationship between
259 income, Father's job, dental floss behavior and brushing behavior in students same Phanthavong
260 study¹³.

261 This study results indicated that perceived self-efficacy, Cues to action, and Commitment to plan
262 were the significant predicting variables which is the key factor of teeth brushing and Brushing
263 behavior at least twice a day, and use of dental floss and Brushing behavior once a day or more.
264 According to the data, respectively the study carried out by Rahnama et al study¹⁴and Hazavei
265 study et al¹⁵ showed that self-efficacy, Cues to action had the highest percent of total variance
266 observed in dental health behaviors.

267 But in there was a constrained correlation between oral health perceptions and elevated
268 perceived benefits in solhi study¹⁶ .Maria et al study on the role of self-efficacy in dental
269 patients' brushing and flossing, found that, barriers emerging, and self-efficacy significantly
270 predicted brushing and flossing behaviors also¹⁷.

271 However, it had no significant relation like the current study with perceived benefits and in
272 contrast to current cues to action¹⁸. Maybe because of the age range of the participants who were
273 in five-grade age and by gender.

274 Within the charkazi study, besides for perceived barriers (with negative correlation), all
275 constructs of HBM were definitely associated with oral health behaviors. Self-efficacy was the
276 most powerful predictor of oral health behavior¹⁹. The kasmaei findings recommend that
277 perceived objective severity and perceived psychological barriers play an important position in
278 adopting acceptable health behavior among younger young people²⁰.

279 Moreover, according to the present study, numerous researches have revealed that commitment
280 to plan has been as the best predictor variable for actual oral health behaviors¹⁹⁻²⁰. Therefore,
281 strategies for enhancing commitment to plan in practice, such as strengthening Self-
282 extinguishing techniques, Enhance commitment, Pursuit of commitment and focus groups
283 discussion could lead to more effective oral health behaviors programs for Iranian students and
284 should be considered in future intervention²¹⁻²². These programs could propose that highly
285 commitment to plan individuals exert greater efforts to empowering individuals to prevent them
286 from returning to unhealthy behavior²³. Pender stated that more commitment to plan could have a
287 much impact on continuing health promotion behaviors²⁴.

288 In this study, the variables of cues to action with a positive relationship were demonstrated to be
289 significant predictors for oral health behaviors among the Iranian students. This finding is
290 supported by many previous studies which found that Cues to action are stimuli that trigger
291 appropriate health behaviors. Cues can be either internal, that is, the perception of bodily states,
292 or external, that is, stimuli from the environment, such as interpersonal interactions or the mass
293 media²⁵⁻²⁶. In the current study, there was also a relationship between Self-efficacy and oral

294 health behaviors. Similar to the present study, Self-efficacy was the most predictive factors of
295 oral health behaviors. These results are consistent with previous studies²⁷⁻²⁹.

296 **Limitations**

297 There are several limitations to this study. First, the statistics used on this evaluation were
298 amassed via a cross-sectional design in addition to assessing oral health behaviors as self-report,
299 in which humans typically might record the conduct better than the real amount. Furthermore,
300 this observes changed into based totally on a comfort sample, so that it's locating of this study
301 might not be generalized to all Iranian students groups to evaluate the real rate of behaviors and
302 effective factor on them. Another limitation of this study is that it was performed in the female
303 sex group.

304 **Conclusions**

305 This study has shown the effectiveness of the health belief model with added commitment to
306 plan construct to predict oral health behavior in female students. So, it seems that the model as a
307 framework for designing training programs to improve students to improve oral health behavior
308 can be used. The finding of this study provides needed data assisting the development of model-
309 based behavioral prevention interventions to encourage student's oral health behavior. Cross-
310 sectional design in addition to evaluating oral health behaviors as self-report is another limitation
311 of the study.
