Abstract: This work *promotes new methods* in Mathematical Modeling, consisting in the use of the methods of Non-standard Analysis in Topoi, having as its *main purpose*, the mathematical definitions of the pseudoparticles from the title, with arguments from Biology/Physiology (Mathematical Neuroscience), Physics (String Theory and Emergent Quantum Mechanics), and Cybernetics (Global Brain, including Natural and Artificial Intelligence). The connections between *brain* and *mind* will be sketched via the genetic/epigenetic interplay. The topoi model the intuitionistic logic (multi-valued) and have been used in Quantum Physics while Non-Standard Analysis in SET (= the Category of sets) has been applied in Mathematical Economics; topics from Theory of Categories were also used in the study of Consciousness; however, the combination topoi - non-standard analysis was never used until now in Applied Mathematics. Another *important objective* is to produce progress in this area of Pure Mathematics also - the build of non-standard analysis in classes of topoi, already used in Physics. We propose the logic of non-standard extensions in topoi as a model of the human thinking (based on infons/receptons), these theories representing new top and very difficult results in Abstract Mathematics either.

Keywords: non-standard analysis, topos theory, artificial intelligence, brain studies, intuitionistic logic

Classification: MSC 18D35, 16B50, 16B70, 18F10, 03B50, 26E35

1. Introduction

Preliminary note This is the version 2 of the paper [25] from the References, whose Section 9., entirely written by Dr. Florin Nichita, became part of Section 3. from <https://arxiv.org/pdf/2002.05345.pdf>, and has been submitted for publication. Moreover, the Section 4. of the present version is new. This generated a change of authors. The remaining part of this version is a shortened form of the previous one, to which we make many references.

This present paper contains both known and new results, because it addresses to an auditorium of a great diversity: neuroscientists, informaticians, physicians, physicists, biologists, mathematicians,... so we tried to write a paper which could be read by different kind of specialists. Even the authors and their collaborators belong to various scientific areas (neuroscience, mathematics, medicine, economics; professors, researchers, students). We hope that we produced an enough self-contained and readable paper by many categories interested in the topics. In the same time, the preprint [25] represents a much more expanded version of this article, from mathematical point of view, collecting most of what we considered as being the necessary mathematical notions. So, the paper shortly re-explain already known notions and results, and it also contains new and original contributions. We present them in what follows. *The main original contribution* is the idea of considering the non-standard extension of the intuitionistic logic (in topoi) as modeling the human thinking, consciousness, and considering *together* both natural and artificial intelligence, as parts of the *global brain*, as explained in Sections 2., 3., and 4. We also *contribute to the development of the Non-standard Analysis in set-type exponential topoi*, in the area of Pure Mathematics, see Theorem 6.2.5. Information and energy represent the two facets of an elementary particle in String Theory (the string vibrates = energy in a specific way (amplitude, frequency, spin,...) = information, in order to give one or another one of the elementary particles). They do not reduce to our brain, neither to our body, they travel freely realising connections between the interior (brain, sensory organs, DNA = genetics) and the exterior (epigenetics) of the human body, generating *the mind*, reciprocally related to *the brain* (see [38], [10]). We deal with these subjects in more detail in Sections 2., 3., and 4. In Sections 5. and 6. we recall the basic notions of our modeling approach (based on *Topos Theory* and its *Non-standard extension*), the examples from 5.2.6. - 5.2.8. being *original*. The interpretation of theories (from mathematical logic, model theory) and of the corresponding categories (models of the theories) as infons, energons, and receptons represents an original approach too. For details concerning these things, see Sections 5. and 7. However, this paper shortly uses some notions, not explicitly introduced here, as: (Quantum)Neural Networks, (Quantum)Turing machines, and further

developments of the Non-standard Analysis in more general topoi. All these things will be considered in a forthcoming paper.

For Topoi Theory we refer to the book [13]. For Model Theory we refer to [7]. For non-standard analysis in the topos **SET** we refer to the book [14]. The topoi model the intuitionistic logic (multi-valued) and have been used in Quantum Physics (see [12] and its references; see also [8]) while Non-Standard Analysis in SET (introduced by A. Robinson [35]) has been applied in Mathematical Economics (see [1] and its references). We propose the logic of non-standard extensions in topoi as a model of the human thinking (based on infons) inspired by the paper [18]. These theories represent top and very difficult results in Abstract Mathematics. We also refer to [10], [17], [36], [38], [41]. Other References will appear later.

All the subjects of this paper are considered in order to justify, both from the point of view of Neuroscience, Cybernetics, and from the view of Physics, the introduction of the pseudoparticles called by us Infons and Receptons, with Energons between them, as a Corpus Callosum in the Brain: to justify how they should be (Sections 2.-4.), and to built mathematically such things (sections 5.-7.).

2. Informatio/Reception : Brain/Mind, Genetics/Epigenetics

In this Section we start to put in evidence, using known and, by many experts recognized results from Biology/Physiology, which relates between them the Information and its Reception with Energy (see [39], [10], [38]).

2.1. Information and Entropy. First of all, information is related to organisation. We say that some systems or objects are more complex than others because we perceive them as containing more information. For example, it is obvious that an epithelial tissue contains more information than a cell. Epithelial cells exhibit distinct polarity, having an apical, a lateral and a basal domain. This organisation involves more information, as the molecular mechanism responsible for this arrangement is required to create a functional barrier between adjacent cells. Following Tom Stonier's idea from [39], information is related to entropy, because the latter is a measurement of organisation. They are exponentially inverse proportional: as a consequence, if - inside a complex system - the entropy decreases, meaning that matter is more organised, the amount of incorporated information increases. We think it is really important to see how this new concept – the incorporated information – influences our lives and more specifically the role it plays in the structure of matter. How do atoms know how to bind together and form a more complex structure? How can a simple stem cell differentiate in so many other types of cells? Information dictates all those processes. Everything contains infons (see section 7, for their mathematical definition, one of the main purposes of this paper). Let's take now, as an example, a sound wave. We can tell for sure that it contains some kind of information, that travels through air until it reaches the human ear. Here it is transformed into a nervous impulse and travels to the brain, where it will be perceived. A sound wave is a mechanical wave that causes local regions of compression and rarefaction through the medium, deviating the local pressure from the equilibrium pressure. Therefore, sound, which is made of information, changes the structure of matter. In neuroscience it is of extreme interest to see how information affects the brain. We, as humans, are born with unconnected neurons. In the first two years, we form synapses while experiencing the world around us. As we grow up, we lose almost 50% of the

already formed synapses, but we also form others while interacting with the environment. How does information influence this process? The more we interact with something, the more powerful the synapse gets. It's like a road through a forest. At first, there's nothing there, but as more and more people go along it, the grass disappears and a path is formed. The same thing happens in the brain. We believe that information extends one's life. During the first part of our lives, the human organism functions in an anti-entropic way. As it gets more organised, the entropy decreases, instead of increasing. However, after this period, the entropy of the human organism continues to increase until it reaches a state of equilibrium with the environment, when the organism dies, because no more *energy exchange* can be done. By increasing the amount of information one takes in, the entropy of the organism decreases, meaning that it prolongs the process of ageing. Thus, learning new things delays the decay of the brain primarily, but of other organs as a consequence as well. For a much more physico-mathematical approach of such kind of things, see Sections 3. and 7. of this paper.

2.2. Information and Reception, Brain and Mind. For further details related to this paragraph, we refer to the books [10], [38]. The Brain is the main organ where the mind is born, but the brain is far from being the only entity involved in the growth of the human mind. The mind is a by-product of the neural networks from the brain (*synapses*), in continuous transformations (some synapses disappear while new ones are born), representing the so-called *plasticity* of the brain. The mind is a by-product of other kind of communications between neurons (and the glial environment), namely the *quantum* networks connected by the so-called microtubules. Certainly, these interactions are between the brain, through the sensory organs, moderated by the information from the DNA molecule (genetics), and the environment (epigenetics). The human being has much information in its DNA, but only some of it will be used in a life-long period. Simplifying, there is information that tells us to start trembling when it is cold (or to sweat when it is hot). However, if we spend a life-time period at the Equator we will never experience the trembling (respectively, if we spend a life-time period at the North pole we will never experience sweating). So, the information from the around 2 m long DNA molecule is read by the environment - epigenetics, the system genetics/epigenetics becoming a kind of (quantum) Turing machine, generating, in particular, the evolution of the mind, which, through plasticity, generates the evolution of the brain, and vice-versa.

We - the humans - think using both consciousness (awareness) and subconsciousness. The Logic of Consciousness is *intuitionistic* (we have, mainly, feelings about things, like about the truth of Conjectures in Mathematics, as an example), and the Reunion between Consciousness and Subconsciousness is a *conservative* extension of consciousness (that is, the subconsciousness does not alter our awareness). So, the logic of human thinking is very similar to the *logic of infons* from Section 7., having as models non-standard objects from non-standard enlargements of topoi - see Section 7. again (based on Sections 5. and 6. also). From a mathematical point of view, it is necessary to understand how the (*quantum*) *neural networks* from the brain (*synapses*) are influenced by the *genetic-epigenetic (quantum) Turing machine*. The Quantum Physics approach is better to be based on truth values than on probabilities, the truth values-approach being used in topoi (see [8]). So, the reunion between consciousness and subconsciousness is modeled by the non-standard logic in enlarged topoi (the IIST logic from section 7., as the Theory of Infons, with models - the Categories of Receptors - as explained in the forthcoming Section 7.).

And, another important thing. A Theorem of Mathematics (for example) is based on the work of many others, so it is a by-product of the *global brain*. The Global Brain includes all the human brains AND technology, used both for getting information from the outside of the direct human perception, and for connecting the brains (libraries, social networks,...) - see section 4. In this case the genetic-epigenetic interaction is between the Global Brain and the Environment, generating a kind of Global Plasticity for the Global Brain, generating a Global Mind (for some details, see Section 4.).

2.3. = 3.2. Information, Energy, and Reception. This paragraph could be introduced here, but it can also belong to the next Section 3., and we preferred to put it there (it is mainly related to Physics, while this Section is mainly related to Biology/Physiology).

3. Information/Reception : String Theory/Emergent Quantum Mechanics

In this Section continue to put in evidence the relation Information - Energy - Reception, using known and, by many experts recognized results from Celestial Mechanics/Physics (see [41], [17], [44], [5]).

3.1. Max Tegmark's Multiverses. Certainly, everything happens in our real world, our real Universe, or our real Multiverse, or... This means that the human brain, human being, global brain,... represent substructures of the highest structure which must exist. There are discussions on what this highest structure is. We recall here the Theory of Multiverses belonging to Max Tegmark (see [41]). Namely, he classifies the notions of Multiverse in 4 categories. First of all, what is an Universe. In these theories the Universe is, by definition, the *visible* Universe. It is a 3D - sphere having its radius of about 14 billion light-years (the approximate period that has passed from the Big-Bang). This sphere is increasing as time passes. A rank 1 Multiverse is a family of Universes which could merge in some future in a bigger Universe. However, the General Relativity does not forbid that the space dilate with a speed higher than the speed of light. This means that two rank 1 Multiverses separated by a volume dilating faster than the speed of light will never merge at the level of a visible Universe. Such a family of rank 1 Multiverses is a rank 2 Multiverse. Because the evolutions are independent to a certain extent, the Universal constants, and even some of the laws of Physics among the rank 1 Multiverses belonging to the rank 2 Multiverse might differ. Further, there are discussions concerning the interpretations of Quantum Physics. One interpretation is based on the Copenhagen Program, based on the collapse of the waves of probabilities when measured (observed), and another one belongs to Hugh Everett III ([11]) saying that the probability waves never collapse, but what happens is in fact a *bifurcation (multifurcation)* of the (rank 2) Multiverse depending on all the possible situations (so, Schrodinger's cat is alive in an Universe and dead in another one, at the same time). This is the so-called many-world interpretation, giving the Tegmark' rank 3 Multiverse (as a quantum family of rank 2 multiverses). And, finally, a rank 4 Multiverse is represented by pure Mathematics, with the Axiom saying that any non-contradictory mathematical theory should have real model(s) in the rank 4 Multiverse (see 5.1.7., 7.1.2., 8.1. also). This tries to explain why our Universe allows life to exist (all the Universal constants should be very, very carefully chosen: the number of Avogadro, the speed of light, the Planck distance or Planck time,...). We will restrict ourselves to a rank 3 Multiverse, as being the quantum family of our observable Universes. While the quantum logic of John von Neumann is considered as being the quantum logic in the Universe (in the sense of the previous definition), the quantum logic in topoi is considered as being the quantum

logic in the Quantum Multiverse (rank 3). This is the logic which we will use, because it is the most appropriate to the human thinking, which is a product of the brain, a substructure of the Uni(Multi)verse (considered one of the most complex such substructures, along with black holes and dark matter). Coming back to the rank 4 Multiverse, it is based on the postulate that there are physical models for any *non-contradictory* mathematical theory. However, the best theories from physics, namely the Einstein' Theory of (General) Relativity (modeling the Universe at the macro-level), and the Quantum Physics (modeling the smallest sub-structures on the Uni(Multi)verse, at the nano-, pico-,... level) are in contradiction in some situations (the quantum entanglement is one of them). At the same time, the two theories should coexist in black holes, for instance. So, a new unifying theory is required, that is a theory unifying the Standard Model (which unifies the Electromagnetic, Strong, and Electroweak forces), a quantic model, with the Gravitation (modeled by the General Relativity). There are currently several approaches in this direction: String Theory, Emergent Quantum Mechanics, Loop Gravity,... We will restrict ourselves to some comments relative to the first two of them.

3.2. Infons and Energons in String Theory. In *String Theory* (see [17]) one considers that any elementary particle is a tiny vibrating chord - string - in a 10-dimensional space, representing the direct product between the Einsteinian 4-dimensional space-time Universe (Einstein-Minkowski real 4-fold) and a complex (projective algebraic) Calabi-Yau 3-fold (so a 6-dimensional real manifold). The Calabi-Yau 3-fold is considered because it has very many symmetries, giving the so-called supersymmetric String Theory, modeling not only bosons (as the initial String Theory did) - that is particles with integer spin, but the fermions as well - particles with half integer but not integer spin. In such a situation the number of elementary particles (quarks, photons, electrons,...) doubled, and one still look for the new elementary particles at CERN, in Geneve. The 6 additional real dimensions of the Universe (Multiverse) are very compacted, and give only very limited possibilities to the string to vibrate, imposing conditions, as wave length, amplitude,... So, a string needs *energy*, in order to vibrate, and *information*, in order to vibrate in a specific way to give one or another of the elementary particles (or antiparticles). In [39] one considers hypothetical elementary particles related to information, calling them *infons*. It is for the first time when the notion has been considered. However, our point of view is based on the fact that these infons represent only one facet of an elementary particle, the other being represented by *energons*, so an elementary particle is like a coin, with two facets: the infon, and the energon. The theory of infons has been already discussed a little in Section 2. After [39], a theory of infons (propositional calculus) has been built by [18]. They came to the conclusion that this theory is a *conservative* extension of the *intuitionistic* logic. However, one can show that the axiomatic of non-standard analysis in an environment using intuitionistic (many-valued) logic represents another similar notion of *infon* which we will use in this paper. So an *infon* is given here by a non-standard enlargement of a topos of the form $\mathbf{SET}^{C^{op}}$ (see Section 5.). The *Theory of infons* is a triplet $\mathcal{I} = (\mathcal{L}, \mathcal{A}, \mathcal{D})$, where \mathcal{L} is the usual language of the intuitionistic non-standard context (see Section 6.), \mathcal{A} is a set of propositions written in the previous language considered as being true (axioms), and \mathcal{D} is a set of deduction rules (as modus ponens is) - see Section 5. - 7. In our sense, *the theory of infons* is the theory of non-standard enlargements of the topoi of type $\mathbf{SET}^{C^{op}}$ (see section 5.). In String Theory, an infon is a non-standard enlargement of a topos of the previous type, while in Emergent Quantum Mechanics an infon remains the theory itself, and the enlargement of the topos of the previous type will be called

recepton. In String Theory we also need to define the energon. We will do this a little later, but, for now, we remark that :

3.3. Infons and Receptons in Emergent Quantum Mechanics. In *Emergent Quantum Mechanics* [44]) one considers that the (potential) Energy is also Information, namely the information that something can move from one place to another. However, we think that we must distinguish between potential (virtual) energy and actual energy (kinetic, caloric, electromagnetic,...). The matter is considered a condensed form of (actual) energy (under the action of the strong nuclear force) related to energy by the well-known formula $E = mc^2$ (both the nuclear fission, from the atomic power plants and the nuclear fusion, from the Sun, generates loss of mass, producing energy). But a stronger argument connecting the (potential) energy with information is represented by The Landauer Principle, quantumising the energy necessary to erase a bit of information (for details see [5]). It means that both energy and information are quantised, and they are somehow inverse proportional (not exponential, as in the case of entropy, see Section 2., but in the same direction, the relation being given by a precise formula, namely $E_{(min)} = k_B T \ln(2)$, where k_B is the Boltzmann constant, T is the temperature of the environment and \ln is the natural logarithm. So, in Emergent Quantum Mechanics everything primordially exists as waves of information = theories in a conservative extension of the intuitionistic logic, all of them being *infons*. Their associated categories (of models) represent then the other facets of the coin, called *receptons* so, in this setting the two faces are *the infon* , and *the recepton*, the category of models of that theory (which is a non-standard enlargement of a topos of a special type, see Section 7.). We, the human beings, are, at the level of our brains, or to the level of the global brain (which include both all the network of the human brains, and the technological discoveries, artificial intelligence included, but also other kind of sensory-type machines) like the radio-sets travelling in a landscape with plenty of electromagnetic waves, and discovering them progressively, function of the increasing quality of the receptor, improved due to the technologies. So, we become progressively aware of the surrounding informational waves (theories) improving progressively our *consciousness* (both at the individual and global level). At the same time, the subconsciousness works, impacting at every step on the consciousness. So, the *receptons* become *the elementary pseudoparticles of the union between consciousness and subconsciousness*, the two facets of the coins being the theory and the associated category (which must be a non-standard topos). In this version of an unification theory, the Uni(QuantumMulti)verse is emerging, being stepwise discovered by brain and global brain through the measurement (collapse) of the intuitionistic informational waves. In fact, Emergent Quantum Mechanics is essentially based on *information* and *consciousness* (which becomes part of Physics !), but there are other important facts around, namely the *non-determinism* (with the meaning that not only the past influences us, but also the future), *the discrete space*, *Gosset Polytope* (see Section 5. also, for a topos representing it), *E8-crystal*, and *golden ratio* $= \Phi = \lim_{n \rightarrow \infty} (F_{n+1}/F_n) (= (1 + \sqrt{5})/2)$, where $(F_n)_{n \in \mathbb{N}}$ is the Fibonacci sequence. The 4D space-time is "pixelated" by the projection on \mathbb{R}^4 of the Gosset polytope from \mathbb{R}^8 with an angle which produce on \mathbb{R}^4 two similar 4-dimensional polytopes such that the quotient of their 4-volumes is equal to Φ . We recall that an *Energon* is either a theory about a potential work (potential energy), so an *Infon*, or a real work (actual energy), which is a *Recepton*.

4. Cybernetical Principles of the Global Brain

In this Section we suggest a notion of the Global Brain, using a Cybernetical approach, relating again Information - Reception - Energy. The approach is both original and based on ideas coming from [27], [28], [45], [9].

4.1. What is the Global Brain? The Global Brain is a bio-technological System composed by physical Receptors organized to generate (electromagnetic, gravitational,...) fields of Energons, fields which interact to the higher levels of Infons and create Consciousness. The Purpose for humans to create a Global Consciousness can be achieved by a smart global architecture of physical Human-Machine System to implement Cybernetic Principles of INFORMATION. As Mihai Draganescu proposed in 1990 there is a frontier between physical level of matter and its Informational dimension called InfoMatter ([9]). At this intersection we identify cybernetic laws which appear in all information systems detected by human sensors (natural and artificial).

4.2. Cybernetic Principles of Information in the Global Brain:

1. *Autonomy of Information*: Information preexists at the highest level of Consciousness and operates individual (finite) and global (infinite).

2. *Universal Connectivity of Information* manifests on the Matrix of all data connections between and inside physical and non physical phenomena on all dimensions.

3. *Free Will versus Information : Human being* relates to Information in terms of list of possible actions and non-actions as a basis for Free Will.

4. *Authorization Access to Information* : at physical level quantum fields interact to create support for Information, access to Information on macro level of Human Beings consists in permissions for entities as Humans, Robots or other Automatic to interchange data according to Free Will Principle.

5. *Exception Handling for Information Ambiguities* : Natural phenomena of information error consists of contradictions inside information with associated correction choices (*Multiple Choices*).

Eric Kandel ([22]) was a recipient of the 2000 Nobel Prize in Physiology or Medicine Nobel Prize for his research on the memory storage in neurons proved that Information is linked inside brain to physical level.

4.3. Global Brain Functions regarding Information are derived from Data Cybernetic Principles ([20]) with the difference Information is a Metadata relevant in terms of utility for a recipient (Human or Robotic).

1. *Information acquisition*: metadata is identified from perception of existing data inside and outside entities (Humans/Robots, at the Receptor Level).

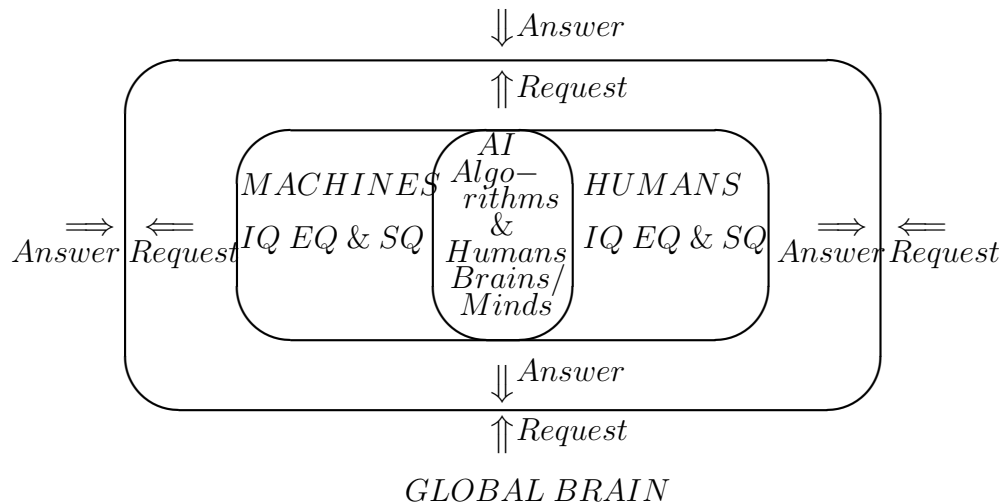

2. *Information processing*: metadata is created through algorithmic processing of data perceived through sensors (at the Infon-Energon Level).

3. *Information Storage*: metadata is physically stored in human brain and IT recipients (natural/artificial neurons and machine storage recipients) (Infon Level).

4. *Information sending and receiving*: metadata interchange between sender and receiver in Request-Answer process (Receptor Level).

4.4. Limits and Outbounds of the Global Brain.

We start with a picture (it is related to picture 7 from [4]):

Machine (AI Algorithms) vs. Humans : a Global Brain Architecture

The Architecture of Global Brain generated by Machine (Artificial Intelligence Algorithms) – Human Beings interactions are inspired by Norbert Wiener's Cybernetic Communication principles ([45]), and have a possible graphical representation as below (M-Hemisphere, H-Hemisphere, corpus AIH, analogous to the left hemisphere, right hemisphere and corpus callosum of the human brain). Based on Stefan Odoblejas vision ([27]) on analogy and models of mental psychology, a Global Brain should attain at least the psychological functions of the human brain. Therefore: Request-Answer is a Cybernetic model to create Bio-Technological Feedback between Global Brain entities at the Knowledge Frontier. In the figure above the membrane of the Global Brain is in fact an invisible Knowledge Frontier towards Global Consciousness, continuously in activity inside the System and above it. Many scientists claim for unified theory in science for the explanations of natural phenomena, one of them is Nassim Harramein ([19]) with Unified Field Theory (see also Section 3.), which connects the Standard Model and Gravitation in a single unifying framework (see also [27], [24], [21]). From this viewpoint, the Global Brain is the instrument to apply and study multiple theories from multiple disciplines: psychology, physiology, informatics, cybernetics, physics, mathematics and others in One Brain Framework. Nikola Tesla stated also that we live in the Age of Electricity ([42]) where electricity is the meeting point for chemists, physicians and physiologists, as the electromagnetic energy can be transmitted wireless and its power conducts mankind to progress. In fact Electricity is a basis for any Global System and the Global Brain can be viewed as an application of Tesla's scientific work. Therefore Tesla's vision of communication services in a Global System have become possible to implement almost a hundred years later due to Internet and Machines ([43]). Therefore the image above is a vision of a complex adaptive system composed by artificial Machines able to manifest Rational, Emotional and Social Intelligence (levels of IQ, EQ, SQ) and Humans also given by nature the same characteristics, the communication being done at the Level of Artificial Intelligence based on Cybernetic Algorithms (certainly, the relatively recent discoveries in the aria of gravitational waves can relate the things with the gravitation/graviton also). The final scope of Global Brain is to be a Knowledge instrument used by Humans to develop more self consciousness in their natural habitat. To preserve the habitat of life with other forms of biological and non biological entities, humans should design a smart and self adaptive system with Ethics and Human Psychological Components. Mihai Golu ([15], [16]) studied the field of neuropsychology and its cybernetic dimension and his work is a startpoint to define

Global Brain to be able to manifest Consciousness at a higher level of performance in comparison to nowadays human society manifestations on all aspects of development.

Regarding Mathematical instrument to design and operate inside Global Brain, the Non Standard Analysis in Topoi is a research startpoint achieved in the following Sections of this work. In this setting, we propose a starting definition for *Infons*, *Energons* and *Receptons*, as working tools used to understand the things better and better. We will formalize in a mathematical language some of the previous comments related to the three pseudoparticles, in accordance with the previous characteristics sketched for them, coming from Biology/Physiology, Physics and Cybernetics. The formalism aims to produce a new mathematical approach for the Problems of Neuroscience, Physics, and Artificial Intelligence. A list with problems from the of Neuroscience is contained in the book [37]. These can be also considered a list of Problem from Physics in Emergent Quantum Mechanics.

5. Theories versus Categories ; Topoi and Mathematical Logic

Although the results from this Section are known, we consider this review Section as representing useful preliminaries for the original part of this paper consisting in the construction of the non-standard extensions in topoi of the SET-type, from the next Section 6., and for the original definitions from Section 7. Here we present, in 5.1. the interplay between Theories and Categories in the classical context of the bivalent logic and Zermelo-Fraenkel(Choice) axiomatics, as precursors of the mathematical definitions of the Infons and Receptons from Section 7. Later, in 5.2 and 5.3 we'll pass to a special kind of categories, namely topoi, with their intuitionistic logic detailed in 5.3. For more details concerning the topics from this section, we refer to [7], [33], [36], [13], [34]. See also the extended version [25], which have the same structure as this paper has, but the notions are presented in more detail.

5.1. Theories versus Categories in ZF(C) axiomatics as precursors on the Mathematical Infons and Receptons.

Definition 5.1.1. A *class* is an arbitrary collection of objects. A *set* is a class which belongs to another class (one avoid in such a way the well-known Russell's paradox, 5.2 from [25]).

Definition 5.1.2. A *language* \mathcal{L} is the family of all formulae, obtained inductively using conjunctions, disjunctions, negations, implications and quantification (existential or/and universal) of the atomic formulae (represented by equality and appartenance of variables, sets, t-uples, $\tau(\sigma)$ with τ and σ from before) (see also 5.3 from [25]).

If \mathcal{N} is a family of classes stable to " \in " (that is $\forall y(y \in \mathcal{N} \wedge x \in y \rightarrow x \in \mathcal{N})$), then we denote by $\mathcal{L}_{\mathcal{N}}$ the restriction of \mathcal{L} to \mathcal{N} (this means that we replace in the classes with those classes from \mathcal{N} only).

Definition 5.1.3. A *sentence* (or *proposition*) is a formula having all the variables bounded (quantified), so there is no free variable. A sentence is *true* or *false* (bivalent logic, see 5.1.9).

Definition 5.1.4. A set of *axioms* is a set \mathcal{A} of sentences, supposed true.

Definition 5.1.5. The *deduction rules* are the rules of inference from a set \mathcal{D} .

Examples 5.1.6.

1. modus ponens (MP): $\frac{p, p \rightarrow q}{q}$;

2. particularization (P): $\frac{\forall x p(x)}{p(y)}$;
3. generalization (G): $\frac{p(y)}{\forall x p(x)}$, etc.

Definition 5.1.7. A *theory* is a triplet $\mathcal{T} = (\mathcal{L}, \mathcal{A}, \mathcal{D})$, with $\mathcal{L}, \mathcal{A}, \mathcal{D}$ as in 5.1.2, 5.1.4, 5.1.5 respectively; in the classical context \mathcal{A} contains the axioms of Classical Logic (bivalent) CL (see 5.1.8) and the well-known Zermelo-Fraenkel(Choice) $ZF(C)$ axioms. We *assume* here, by definition, that a *theory* has at least one model (this represents a compatibility with Tegmark's Rank 4 Multiverse, see Section 3.), which is not automatic for the theories of order at least 2 (see 5.1.13).

Definition 5.1.8. A *classical logic* (CL) is a theory having the following axioms:

Then -1: $A \rightarrow (B \rightarrow A)$.

Then -2: $(A \rightarrow (B \rightarrow C)) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C))$.

And -1: $A \wedge B \rightarrow A$.

And -2: $A \wedge B \rightarrow B$.

And -3: $A \rightarrow (B \rightarrow (A \wedge B))$.

Or -1: $A \rightarrow A \vee B$.

Or -2: $B \rightarrow A \vee B$.

Or -3: $(A \rightarrow C) \rightarrow ((B \rightarrow C) \rightarrow (A \vee B \rightarrow C))$.

Not -1: $(A \rightarrow B) \rightarrow ((A \rightarrow \neg B) \rightarrow \neg A)$.

Not -2: $A \rightarrow (\neg A \rightarrow B)$ (or $\perp \rightarrow B$, \perp false).

Not -3: $A \vee \neg A$.

Remark 5.1.9. We recall from ZF list the following axioms only (see 5.10-5.14 from [25]):

Extensionality (E): $\forall x \forall y [\forall z (z \in x \leftrightarrow z \in y) \rightarrow x = y]$

Regularity (R): $\forall x [\exists a (a \in x) \rightarrow \exists y (y \in x \wedge \neg (\exists z (z \in y \wedge z \in x)))]$

Specification (S): $\forall z \forall \omega_1 \forall \omega_2 \dots \forall \omega_n \exists y \forall x [x \in y \leftrightarrow ((x \in z) \wedge \varphi)]$, where φ is a formula in $\mathcal{L}_{\mathcal{M}}$, with the free variables among $z, \omega_1, \dots, \omega_n$ and having y as a bounded variable. In particular there are sets of the form $\{x | \varphi(x)\}$; note that this axiom allow us to consider such kind of sets only if they are subsets of a bigger set, avoiding in such a way the Russell' paradox. Moreover, this axiom allow us to build the *empty set*, specifically

Remark 5.1.10. $\emptyset = \{x \in y | x \in x \wedge \neg (x \in x)\}$ (the *empty set*). Moreover, the empty set is *unique* (does not depend on y) by the Axiom (E).

Infinity (I) (Peano): $\exists X [\emptyset \in X \wedge \forall y (y \in X \rightarrow S(y) \in X)]$, where $S(\omega) := \omega \cup \{\omega\}$ (the *successor* of ω).

Definition-Remark 5.1.11. $\mathbb{N} :=$ the smallest X as before (= the set of *natural numbers*).

Definition 5.1.12. Let T be a set (possibly $T = \emptyset$). Then $\mathcal{U} = \mathcal{U}(T) := \bigcup_{n=0}^{\infty} U_n(T)$, where $U_0(T) = T$ and $U_{n+1}(T) = U_n(T) \cup \mathcal{P}(U_n(T))$, $\forall n \geq 0$. This is *the Universe generated by T* (one can consider a bigger Universe, where the union is taken over all the ordinals, by transfinite recurrence - the von Neumann Universe - but we don't need it now). It is constructed from the set T , using ZF axioms. We *remark* here that, even when $T = \emptyset$, we have $0 = \emptyset \in U_0$, and, if $\omega \in U_n$, then $S(\omega) = \omega \cup \{\omega\} \in U_{(n+1)}$, so $\mathbb{N} \subset \mathcal{U}(\emptyset)$. Then, take $T = \mathbb{N}$. We get, using the standard constructions of the number fields, that all of them ($\mathbb{Z}, \mathbb{Q}, \mathbb{R}, \mathbb{C}$) are contained in $\mathcal{U}(\mathbb{N})$, by the definition of $\mathcal{U}(\mathbb{N})$ and the ZF axioms. Continuing,

it is easy to see that, in fact, all the necessary mathematical structures can be progressively built starting with the empty set \emptyset (whose existence is postulated by ZF), using the $ZF(C)$ axioms, in higher and higher Universes as before.

Definition 5.1.13. A language $\mathcal{L}_{\mathcal{U}}$, associated with the previous Universe \mathcal{U} can be defined as in 5.1.2. If the quantifiers applies to $U_0(T) = T$ only, we call the resulting language, denoted by \mathcal{L}_T , a *first order language*, if the quantifiers applies to $U_1(T)$ only, we call the resulting language a *second order language*, denoted by $\mathcal{L}_{U_1(T)}$,...,if the quantifiers applies to $U_{n-1}(T)$ only, we call the resulting language a *n-th order language*,..., in this terminology, $\mathcal{L}_{\mathcal{U}}$ being called a *higher order language*.

Examples of Theories 5.1.14. $\mathcal{T} = (\mathcal{L}, \mathcal{A}, \mathcal{D})$.

1. *The theory of sets:* $(\text{Set}) = (\mathcal{L}, CL + ZF, MP)$;
2. *The theory of groups:* $\mathcal{G} = (\mathcal{L}, \mathcal{A} = ZFC + CL + 1) - 4, MP)$, where:
 - 1) $*$: $G \times G \rightarrow G$, function;
 - 2) $\forall x \forall y \forall z [(x * y) * z = x * (y * z)]$;
 - 3) $\exists e \forall x (x * e = e * x = x)$;
 - 4) $\forall x \exists x' (x * x' = x' * x = e)$.

Similarly for 3.-... *The theory of rings, Theories of fields, of vector spaces, of partially ordered sets,...*

5.1.15. We recall that we assumed that all our theories have models (in the case of the first-order language it is known that a theory has a model iff it is not contradictory, that is there is no sentence p such that both p and its negation are deducible).

Examples 5.1.16.

1. $(\mathbb{Z}, +)$ is a model for the theory of groups; (\mathbb{Z} = the set of integers);
2. $(\mathbb{Z}, +, \cdot)$ is a model for the theory of rings; and so long.

Definition 5.1.17. The family of all the models (or of a set of models) of a theory, together with the "dictionaries" between them (functions, or other objects, compatible with the structure of the theory) gives a *category* $\mathcal{C}_{\mathcal{T}}$ associated to the theory \mathcal{T} .

Examples 5.1.18.

1). **Gr** (category of groups): contains all (or a set of) groups, denoted by $Ob(\mathbf{Gr})$, and the morphisms between them, that is $Hom_{Gr}(G, H) = \{f : G \rightarrow H | f(x *_G y) = f(x) *_H f(y), \forall x, y \in G\}$.

2). **Ring** (category of rings): $Ob(\mathbf{Ring})$ = a class (or set) of rings, $Hom_{Ring}(R, S) = \{f : R \rightarrow S | \forall x \forall y [f(x + y) = f(x) + f(y)] \wedge [f(x \cdot y) = f(x) \cdot f(y)]\}$, $f(1_R) = 1_S$. Similarly for fields (the category **Field**), vector spaces (the category **Vect**), ordered sets (the category **POSET**), and so long.

Definition 5.1.19. (Theory of Categories). A *category* \mathcal{C} is a 4-uple $(Ob(\mathcal{C}), (Hom_{\mathcal{C}}(A, B))_{A, B \in Ob(\mathcal{C})}, \circ, (1_X)_{X \in Ob(\mathcal{C})})$ satisfying the axioms:

- (i) $\circ : Hom_{\mathcal{C}}(A, B) \times Hom_{\mathcal{C}}(B, C) \rightarrow Hom_{\mathcal{C}}(A, C)$
 $(f, g) \mapsto g \circ f$ such that $(h \circ g) \circ f = h \circ (g \circ f) \forall f, g, h$ for which all the compositions are defined;
- (ii) $\forall X \forall Y, X, Y \in Ob(\mathcal{C}), \forall f \in Hom_{\mathcal{C}}(X, Y)$, the following diagrams are commutative:

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ 1_X \downarrow & & \downarrow 1_Y \quad (\text{i.e. } 1_Y \circ f = f \circ 1_X). \\ X & \xrightarrow{f} & Y \end{array}$$

Remark 5.1.20. Any category (the models of a theory) is a model of the theory of categories, as are, for instance, the examples 5.1.16.

Remark 5.1.21. The *category* associated to the theory of categories is a category of categories, named **CAT**, that is:

$\text{Ob}(\mathbf{CAT}) = \text{categories}$

$\text{Hom}_{\mathbf{CAT}}(\mathcal{C}_1, \mathcal{C}_2) = \text{the functors (see 5.1.22) from } \mathcal{C}_1 \text{ to } \mathcal{C}_2, \text{ with "o" and } 1_{\mathcal{C}} \text{ defined canonically.}$

Definition 5.1.22. Let \mathcal{C}_1 and \mathcal{C}_2 be two categories. A *functor* $F : \mathcal{C}_1 \rightarrow \mathcal{C}_2$ is acting on objects: $F(A) \in \text{Ob}(\mathcal{C}_2)$, $\forall A \in \text{Ob}(\mathcal{C}_1)$ and on morphisms: $F(f) \in \text{Hom}_{\mathcal{C}_2}(F(X), F(Y))$, $\forall f \in \text{Hom}_{\mathcal{C}_1}(X, Y)$, being compatible with compositions and identities, that is:

- (i) $F(g \circ f) = F(g) \circ F(f)$, $\forall f, g$ such that the composition is defined, and
- (ii) $F(1_X) = 1_{F(X)}$, $\forall X \in \text{Ob}(\mathcal{C}_1)$.

Remark 5.1.23. The previous definition introduce both the notion of morphism in **CAT**, and the *theory of functors* also. So, one expects to get the *Category of functors* also. Indeed,

Definition 5.1.24. Let \mathcal{C}_1 and \mathcal{C}_2 be two categories. We define the category $\mathcal{C}_2^{\mathcal{C}_1}$ as follows:

- $\text{Ob}(\mathcal{C}_2^{\mathcal{C}_1}) = \{F : \mathcal{C}_1 \rightarrow \mathcal{C}_2 | F \text{ functor}\}$
- $\text{Hom}_{\mathcal{C}_2^{\mathcal{C}_1}}(F_1, F_2) = \{h : F_1 \rightarrow F_2 | h \text{ is a natural transformation}\}.$

The composition and the identities are defined canonically.

Here we need the following:

Definition 5.1.25. If $F_1, F_2 \in \text{Ob}(\mathcal{C}_2^{\mathcal{C}_1})$, a *natural transformation* $h : F_1 \rightarrow F_2$ is a collection $h = (h_X)_{X \in \text{Ob}(\mathcal{C}_1)}$ of morphisms $h_X : F_1(X) \rightarrow F_2(X)$, $h_X \in \text{Hom}_{\mathcal{C}_2}(F_1(X), F_2(X))$, $\forall X \in \text{Ob}(\mathcal{C}_1)$

such that $\forall f \in \text{Hom}_{\mathcal{C}_1}(X, Y)$ the diagrams
$$\begin{array}{ccc} F_1(X) & \xrightarrow{h_X} & F_2(X) \\ F_1(f) \downarrow & & \downarrow F_2(f) \\ F_1(Y) & \xrightarrow{h_Y} & F_2(Y) \end{array}$$
 commutes (i.e. $h_Y \circ F_1(f) = F_2(f) \circ h_X$).

Remark 5.1.26. We insisted till now to get categories from theories, but the converse also works, axiomatizing the things. So, the theories and the categories are the two faces of the same thing, but they represent different notions.

Definition 5.1.27. Let \mathcal{C} be a category. The *dual* category of \mathcal{C} , denoted by \mathcal{C}^{op} is the category having:

- $\text{Ob}(\mathcal{C}^{op}) = \text{Ob}(\mathcal{C})$;
- $\text{Hom}_{\mathcal{C}^{op}}(X, Y) = \text{Hom}_{\mathcal{C}}(Y, X)$, $\forall X, Y \in \text{Ob}(\mathcal{C})$ (reversing the arrows).

5.1.28. We will assume further that the reader is familiar with parts of the Theory of Categories. If not, we produced the manuscript [25] (Sections 5. and 6.) exactly for those readers (from Neuroscience, or some Physicists, Economists) which feel better to have all the necessary things collected in only one place. A much more detailed treatment is presented in [13]. In particular, we assume as known the notions of *initial object* (usually denoted by **0**), *final object* (usually denoted by **1**), *monomorphism*, *epimorphism*, *isomorphism*, *subobject of an object*, *direct product*, *direct sum*, *equalizer*, *coequalizer*, *inductive limit*, *projective limit*, *pullbacks*, *pushouts*, *exponentiation* (usually denoted by $\mathbf{X}^{\mathbf{Y}}$, with \mathbf{X}, \mathbf{Y} objects), *subobjects classifier* (usually denoted by Ω). The notions product and sum, initial and final, epi and mono, co... and without co, pull and push, inductive and projective,... are dual notions. An example is given by the next

Definition 5.1.29. A functor $F : \mathcal{C}_1 \rightarrow \mathcal{C}_2^{op}$ is called a *cofunctor* $F : \mathcal{C}_1 \rightarrow \mathcal{C}_2$. It satisfies $F(g \circ f) = F(f) \circ F(g)$, $\forall f, g$ (instead of $F(g \circ f) = F(g) \circ F(f)$, $\forall f, g$ as a functor does). This is the first example of a pair of *dual* notions (functor vs. cofunctor). We'll see other examples in section 6.

5.2. Topos Theory. Now we pass to the main notions used in this paper:

Definition 5.2.1. An *elementary topos* is a category \mathcal{E} such that:

- (T1) \mathcal{E} has finite inductive limits;
- (T2) \mathcal{E} has finite projective limits;
- (T3) \mathcal{E} has exponentiation;
- (T4) \mathcal{E} has subobjects classifier. (see [13], [25])

Remark 5.2.2. It can be shown that the conditions required in the definition of a topos, implies the existence in such categories of the objects having the propriety to be any of the objects from 5.1.28. (so, there exists initial and final objects, (finite) direct products and sums, equalizer, coequalizer, pullbacks, pushouts, power object of any two objects,...)

Examples of topoi 5.2.3. 1). The category **SET** of sets.

2). The category of n -uples of sets with the morphisms defined on components. This can be written as $\mathbf{SET}^{\mathbf{n}}$, where \mathbf{n} is the discrete category having $Ob(\mathbf{n}) = \{1, 2, \dots, n\}$, $1, 2, \dots \in \mathbb{N}$ as objects and only the identities as morphisms (this category is of type 5.1.24).

3). $\mathbf{SET}^{C^{op}}$ is also a topos. The previous example is a particular case, when $\mathcal{C} = \mathbf{n}$.

Definition 5.2.4. A topos of the form 3). will be called *exponential topos*. If the topos from 3) is obtained for a category \mathcal{C} having a finite number of objects and morphisms, we will call the topos **SET-type topos**.

Remark 5.2.5. In Section 6. we will construct non-standard extensions for **SET**-type topoi, as finite-generalization of the non-standard analysis in the topos **SET**, introduced in [35], see also [14], [25]. This will be an original mathematical contribution. The general case of the exponential topos will be considered in Part II of this work.

5.2.6. Oriented graphs as topoi of SET-type. An oriented graph $\vec{\mathcal{G}}$ consists in a finite number of points $A = \{A_1, A_2, \dots, A_m\}$ (the word point, is only formally used, the elements of A are not necessarily geometric entities), some (or all) of them being joined with some others (or all) of them by oriented segments (arrows); we note that the elements of A can be categories, and the arrows can be functors (for example). We will suppose here, additionally, that for each i, j , $i, j \in \{1, \dots, n\}$ there is at most one arrow, either from A_i to A_j or from A_j to A_i , that the path of two consecutive arrows can be replaced with an arrow, and we implicitly assume the existence of an unique arrow from A_i to itself, for any i as before, namely the identity arrow (which has no orientation). We can organize this graph as a category of type \mathbf{n} with some additional morphisms: we add to \mathbf{n} a morphism from i to j , $i, j \in \mathbf{n}$ iff there is an arrow from A_j to A_i in $\vec{\mathcal{G}}$. Let's denote this new category by $\mathbf{n}_{\vec{\mathcal{G}}}$. Then the **SET**-type topos $\mathbf{SET}^{\mathbf{n}_{\vec{\mathcal{G}}}^{op}}$ can replace the given graph. In fact one can work with a category of n -uples of sets, (X_1, \dots, X_n) requesting additionally that $X_i \subset X_j$ whenever there is an arrow from A_i to A_j in $\vec{\mathcal{G}}$. This approach can be used to study various kind of graphs, in particular *graph neural (quantum) networks* of various kinds (optical, convolutional,...) with the quantum aspects modeled in topoi. Such a development is related to *deep learning, artificial intelligence, quantum computers* (starting with the

quantum Turing machine). Moreover, Mathematical Game Theory is also related to Graph Theory, and some economical applications can be obtained, for instance related to the new area of *Neuroeconomics*. There are also connections between graphs and the evolutionary games (with applications in the study of climate change, evolutionary biology,...).

5.2.7. Geometric topoi. One can use the previous topos-interpretation of the oriented graphs to build Geometric Topoi. Let's consider the following oriented tetrahedron :

We denote now by \vec{T} the oriented graph given by the previous tetrahedron, and by $\mathbf{n}_{\vec{T}}$ the discrete category \mathbf{n} at which we added the additional morphisms $2 \rightarrow 1$, $3 \rightarrow 1$, $4 \rightarrow 1$, $3 \rightarrow 2$, $4 \rightarrow 2$, $4 \rightarrow 3$. Then the previous tetrahedron can be recognized in the topos $\mathbf{SET}^{\mathbf{n}_{\vec{T}}^{op}}$ or, alternatively, in the topos whose objects are the quadruplets $\{(A_1, A_2, A_3, A_4) | A_1, A_2, A_3, A_4 \text{ sets, with } A_1 \subset A_2, A_1 \subset A_3, A_1 \subset A_4, A_2 \subset A_3, A_2 \subset A_4, A_3 \subset A_4\}$ and having as morphisms quadruplets of functions compatible with restrictions. In such a way, one can represent in topoi any polygon, polyhedron, and polytope from \mathbf{R}^n , $n \geq 2$.

5.2.8. Gosset polytope. An important polytope in Emergent Quantum Mechanics (where the consciousness become part of Physics) is the Gosset polytope (see the final part of section 4.). It is a polytope $P \subset \mathbf{R}^8$ having 240 vertices, with coordinates $(\pm 2, \pm 2, 0, 0, 0, 0, 0, 0)$, with any combination of signs and the 2's on any two positions (112 vertices) and $(\pm 1, \pm 1, \pm 1, \pm 1, \pm 1, \pm 1, \pm 1, \pm 1)$, by taking an even number of minus signs (128 more vertices). The vertices of the analogue of the Gosset polytope in \mathbf{R}^3 has the coordinates $(\pm 2, \pm 2, 0)$, $(\pm 2, 0, \pm 2)$, $(0, \pm 2, \pm 2)$ (12 vertices), and $(-1, 1, 1)$, $(1, -1, 1)$, $(1, 1, -1)$, $(-1, -1, -1)$ so, this polyhedron has 16 vertices. They form 3 squares of radius 4, with the centers in the center of the axes of coordinates and sitting in the planes xOy , yOz , zOx respectively (O is the center of the axes), and having the edges parallel with the axes of coordinates, and a regular tetrahedron. The 12 vertices of the three squares are the middle of the edges of a cube having edges of length 4, the center in O, and the faces parallel with the planes of coordinates. So, this polyhedron is determined by a cube and a (regular) tetrahedron. It can be represented as a topos using the method from 5.2.7. But even the Gosset polytope from \mathbf{R}^8 can be represented in such a way once we give orientations to its edges. However, the group of symmetries of the Gosset polytope is a group which can be found in the structure of the (-2) curves from a degenerate del Pezzo surface of degree d . However, we will deal with this subject in forthcoming paper, based on [29], [30].

5.3. Intuitionistic Logic in Topoi. It is well known the connection between CL (see 5.1.8.) and the Boolean Algebras (resp. lattices), $\mathcal{A}=(A, +, \cdot, -, 0, 1)$ (resp. $\mathcal{B}=(A, \vee, \wedge, ', 0, 1)$, with the operations defined canonically: \sup, \inf, \dots), see [36] ([25] might be also useful). We'll not insist here.

Definition 5.3.1. The axioms of (IL) are (notations from 5.1.8.):

Then - 1, Then - 2;

And - 1, And - 2, And - 3;

Or - 1, Or - 2, Or - 3;

Not 2.

Definition 5.3.2. A poset (H, \leq) is called a *Heyting lattice* if it is a bounded lattice (so, for any $a, b \in H$ there exists $a \wedge b = \inf\{a, b\}$, $a \vee b = \sup\{a, b\}$, there exists $0, 1 \in H$ such that $0 \leq x \leq 1$ for any $x \in H$) satisfying the following conditions a) - e), when replacing $+$ and \cdot by \vee and \wedge (0,1 remain the same), and having an operation \rightarrow satisfying:

$$\forall a, b, c, (a \wedge b \leq c \Leftrightarrow a \leq (b \rightarrow c)) \quad (1).$$

Here: a) $\forall x \forall y (x + y = y + x)$; $\forall x \forall y : (x \cdot y = y \cdot x)$;

b) $\forall x \forall y \forall z [(x + y) + z = x + (y + z)]$; $\forall x \forall y \forall z [(x \cdot y) \cdot z = x \cdot (y \cdot z)]$;

c) $\forall x \forall y \forall z [x \cdot (y + z) = x \cdot y + x \cdot z]$; $\forall x \forall y \forall z [x + (y \cdot z) = (x + y) \cdot (x + z)]$;

d) $\forall n (x + 0 = 0 + x = x)$; $\forall n (x \cdot 0 = 0 \cdot x = 0)$;

e) $\forall n (x + 1 = 1 + x = 1)$; $\forall n (x \cdot 1 = 1 \cdot x = x)$;

So, a Heyting lattice is a 6-uple $(H, \vee, \wedge, \rightarrow, 0, 1)$ as before. A *Heyting algebra* is a 6-uple $(H, +, \cdot, \rightarrow, 0, 1)$ obtained by replacing \vee and \wedge with $+$ and \cdot . Given a Heyting algebra we get from it a poset which is a Heyting lattice, putting $a \leq b \Leftrightarrow a \rightarrow b = 1$.

A *monadic Heyting algebra* (abbreviated MHA) is an algebraic structure $(H, +, \cdot, \rightarrow, 0, 1, \exists, \forall)$ where $(H, +, \cdot, \rightarrow, 0, 1)$ is a Heyting algebra, \exists is a *closure operator* on H (this means, it satisfies the following (i)-(iv)), \forall is an *interior operator* on H (this means, it satisfies the following (i)'-(iv)'), and

(v) $\forall \exists a = \exists a$, for any $a \in H$;

(vi) $\exists \forall a = \forall a$, for any $a \in H$;

(vii) $\exists (\exists a \wedge b) = \exists a \wedge \exists b$, for any $a, b \in H$, where

(i) $\exists 0 = 0$;

(ii) $a \leq \exists a$, for any $a \in B$ (recall that $a \leq b$ iff $a \cdot b = a$, iff $a + b = b$, iff $a \rightarrow b = 1$; we recall that $a \rightarrow b = \bar{a} + b$);

(iii) $\exists a = \exists \exists a$, for any $a \in B$;

(iv) $\exists (a \vee b) = (\exists a) \vee (\exists b)$, for any $a, b \in B$, and

(i)' $\forall 1 = 1$;

(ii)' $\forall a \leq a$, for any $a \in B$;

(iii)' $\forall a = \forall \forall a$, for any $a \in B$;

(iv)' $\forall (a \wedge b) = (\forall a) \wedge (\forall b)$, for any $a, b \in B$.

Note. Here $a \wedge b = a \cdot b$, $a \vee b = a + b$ (we preferred to use the logic related symbols).

Remark 5.3.3. The condition (1) from 5.3.2. is satisfied in the Boolean algebra case for $b \rightarrow c = b' \vee c$. If, in the definition of MHA we have $H=B$ = Boolean algebra, then we use the notation MBA (monadic

Boolean algebra). In this case, the existence of the closure operator is equivalent to the existence of the interior operator, and the conditions (v) - (vii) from before are automatically satisfied.

Remark 5.3.4. Any Heyting algebra (lattice) satisfies the axioms of (IL) from 5.2.1.

Examples 5.3.5. 1). All the Boolean algebras (lattices) are Heyting algebras (lattices). Any MBA is MHA.

2). An example of a Heyting algebra which is not Boole can be found in [25], at 6.5. 2).

3). Another example of Heyting non-Boole algebra is : If (X, τ) is a topological space. If $A \subset X$, we define the *interior* of A as being the set $\{a \in A | \exists D_a \in \tau \text{ s.t. } a \in D_a \subset A\} := \overset{\circ}{A}$. Then $(X, \vee, \wedge, \rightarrow, 0, 1)$ is a Heyting algebra which is not Boolean in general, where: for $A, B \in \tau$, $A \vee B := A \cup B \in \tau$, $A \wedge B := A \cap B \in \tau$, $A \rightarrow B := \widehat{B \setminus A} \in \tau$, $0 = \phi \in \tau$, $1 = X \in \tau$.

Definition 5.3.6. We can define a *negation* in Heyting algebra, putting $\neg a := a \rightarrow 0$ (this is compatible with the Boolean case), but it does not satisfy the principle of double negation and other principles (tertium non datur, reductio ad absurdum, De Morgan's laws).

Remark 5.3.7. Given a topos \mathcal{E} , one can define, for any $X \in Ob(\mathcal{E})$, operations on its subobjects, similar in some sense with the union, intersection, complementary, empty set, total set from the case **SET**. In a general topos, for any $a, b \in Sub_{\mathcal{E}}(X)$ (Sub = the family of subobjects) one defines: union $a \cup b$ (using the existence of the equalizers and direct sums), intersection $a \cap b$ (using the existence of pullbacks), implication $a \rightarrow b$ (using the existence of the exponentiations), minimal object = $0 \cap X$, and maximal object = $1 \cap X$. In the case of **SET**, the usual operations between sets gives a structure of Boolean algebra. In a general topos, the previous operations gives a structure of a Heyting algebra. We get an analogue of the power set of X . We suppose all these things as known. For details, see [13], [34] (the constructions are included in 6.37 - 6.42 from [25] also).

Remark 5.3.8. For the topos **SET**, the subobjects classifier is $\Omega = \{0, 1\}$ (via the usual characteristic function), and, in CL and ZF(C) axiomatics, the number of truth values is the cardinal of $Hom_{\mathbf{SET}}(1, \Omega)$ (here 1 =any singleton), that is 2. For a general topos, on Ω one can define logic operators $\vee, \wedge, \rightarrow, \perp, \top$ using the so called Ω -axiom appearing in the definition of the subobjects classifier. Then $(\Omega, \vee, \wedge, \rightarrow, \perp, \top)$ is a Heyting algebra, in general. When it is a Boole algebra, one says that the topos \mathcal{E} is a Boolean topos. We again assume these things as known. Details, again in [13], [34] (the constructions are also included in 6.43, 6.44 from [25]). Moreover, one can give to Ω a structure of MHA also. See [6], [40] (referred in [13], pag. 457). See also 6.51 - 6.53 from [25].

Remark 5.3.9. Fix a language \mathcal{L} , and, for a given topos \mathcal{E} having Ω as subobjects classifier, we assign to any atomic sentence a from \mathcal{L} (see 5.1.2, 5.1.3) an element $V(a)$ from $Hom_{\mathcal{E}}(1, \Omega)$. Then extend this association V to all the sentences from \mathcal{L} , using the logical connectiveness for \mathcal{L} , and, correspondingly, the operators from 5.3.8. in $Hom_{\mathcal{E}}(1, \Omega)$ ($V(p \vee q) = V(p) \vee V(q)$, with the \vee from the left being the logical connector, and \vee from the right being the connector from 5.3.8., similarly for the other operations \wedge , etc.). This extends the known Boolean *valuations*. We remark that $card(Hom_{\mathcal{E}}(1, \Omega))$ represents the number of truth values in \mathcal{E} (possible infinite). They are called the *global sections* of Ω .

Example 5.3.10. Consider the **SET**-type topos \mathcal{E} , whose objects are $\{(A_1, A_2, A_3, A_4) | A_1 \subset A_2, A_3 \subset A_4, A_1 \subset A_3, A_2 \subset A_4\}$, with morphisms quadruplets of functions, compatible with the existing inclusions. In this cases $card(Hom_{\mathbf{SET}^4}(1, \Omega)) = 6$, the sections being $\{(0, 0, 0, 0) < (0, 0, 0, 1) < (0, 0, 1, 1) < (0, 1, 0, 1) < (0, 1, 1, 1) < (1, 1, 1, 1)\}$ (lexicographical order); the

characteristic function of the quadruplet of sets is the corresponding quadruplet of usual characteristic functions (for sets). So the intuitionistic logic in this topos has 6 truth values. In such a way we can built as many examples as we want. In particular we can prove that, for any natural number n , there is a topos whose intuitionistic logic has exactly n truth values. One example of such a topos is the topos having as objects the n -uples of sets $\{(A_1, \dots, A_n) | A_1 \in A_2 \in \dots A_n\}$ and as morphisms n -uples of functions, compatible with the inclusions. The the truth values are $\{(0, \dots, 0) < (0, \dots, 0, 1) < (0, \dots, 0, 1, 1) < \dots < (1, \dots, 1)\}$, so $(n+1)$ truth values. For more details and examples, see [13], [34] (see also 5.46 - 5.52 and 6.45 - 6.53 from [25]).

6. Non-standard Analysis in SET-Type Topoi

We start this Section be shortly recalling (in 6.1) the notion of *non-standard enlargement* of a standard universe (see 5.1.12) $\mathcal{U} = \mathcal{U}(T)$ (with its mathematics), $\mathcal{U} \subset {}^*\mathcal{U}$, as introduced by Abraham Robinson in [35]. This works in the category (topos) **SET**. Modern details can be found in [14]. See also [32], [31]. Most of the results from [14] are also presented in 7.20 - 7.45 from Section 7. of [25]. Then, in 6.2, we extend the things to **SET**-type topoi, introducing for the first time non-standard extensions for such kind of topoi. These are original results from pure mathematical point of view.

6.1. The Non-standard extensions in SET. Let $\mathcal{U} = \mathcal{U}(T) \xrightarrow{*} \mathcal{U}' = \mathcal{U}(T')$ (${}^*(T) \subset T'$) a monomorphism (injective map) of universes. Let's denote by ${}^*\mathcal{U} := {}^*(\mathcal{U}) \subseteq \mathcal{U}'$ and by *a the image of a , ${}^*a := {}^*(a)$, $\forall a \in \mathcal{U}$. For a sentence φ in $\mathcal{L}_{\mathcal{U}}$, let's denote by ${}^*\varphi$ the sentence in $\mathcal{L}_{\mathcal{U}'}$ obtained by keeping unchanged the primary relations \in and $=$ as well as the logical quantifiers $\forall, \wedge, \neg, \rightarrow, \exists$, and replacing all the constant symbols $a \in \mathcal{U}$ by ${}^*a \in \mathcal{U}'$. One requests that $*$ satisfies the axioms:

- ${}^*a = a$, $\forall a \in T$ (if $\mathcal{U} = \mathcal{U}(T)$, for $T = \emptyset$ this condition doesn't exist);
- ${}^*\emptyset = \emptyset$;
- S, T : An $\mathcal{L}_{\mathcal{U}}$ - sentence φ is true $\Leftrightarrow {}^*\varphi$ is true as $\mathcal{L}_{\mathcal{U}'}$ - sentence; the \Rightarrow is called **transfer (T)**, and \Leftarrow is called **standardization (S)**;

• **I (idealisation)**: If $\mathcal{R} \in \mathcal{U}$ is any *finitely satisfiable* binary relation (i.e. $\forall n \forall x_1, \dots, x_n \exists y (y \mathcal{R} x_1 \wedge \dots \wedge y \mathcal{R} x_n)$), then ${}^*\mathcal{R}$ is *globally satisfiable* (i.e. $\exists y' \forall x (y' \mathcal{R} x)$). We should remark that the x 's and y run inside \mathcal{U} , while y' runs through \mathcal{U}' (${}^*x = x$, $\forall x \in \text{dom } \mathcal{R}$, $y \in \mathcal{U}$, $y' \in \mathcal{U}'$). We note that the order of the variables is not important, because, if $\mathcal{R} = \mathcal{R}(x, y)$ is a binary relation, so is $\mathcal{R}(y, x) = \mathcal{R}^{-1}$.

In the previous situation, one call the extension $\mathcal{U} \xrightarrow{*} \mathcal{U}'$, a non-standard extension of \mathcal{U} . We note that the inclusion $\mathcal{U}(T) \subset \mathcal{U}({}^*T)$, (${}^*T \in \mathcal{U}'$) is a non-standard extension ([14], Enlargement Theorem, page 185).

Remark 6.1.1. 1. If $\mathcal{U} = \mathcal{U}(T)$ and $\mathcal{U}' = \mathcal{U}(T')$ are Universes, with $T \subset T'$, then take T'' such that $T \subset T''$, $T' \subset T''$ and let $\mathcal{U}'' = \mathcal{U}(T'')$. Then $\mathcal{L} := \mathcal{L}_{\mathcal{U}} = \mathcal{L}_{\mathcal{U}''}|_{\mathcal{U}}$ and $\mathcal{L}' := \mathcal{L}_{\mathcal{U}'} = \mathcal{L}_{\mathcal{U}''}|_{\mathcal{U}'}$ (notations from 5.1.13). We call $\text{ZFC} + \text{CL} + \text{I} + \text{S} + \text{T} := \text{IST}$ (*internal set theory*), with CL from 5.1.8., ZFC from 5.1.9., and I, S, T from before. The triplet $(\mathcal{L} = (\mathcal{L}_{\mathcal{U}}, \mathcal{L}_{\mathcal{U}'}), \text{IST}, \mathcal{D} = \{MP, G, P\})$ (see 5.1.6.) represents the *Theory of non-standard extensions*. We point out that this theory has a *higher order logic*, that is, it is possible to quantify over any entity.

2. If \mathcal{U} has ZFC then $^*\mathcal{U}$ has IST as axiomatics. Moreover, a sentence φ in $\mathcal{L}_{\mathcal{U}}$ *conserves* its truth value (0 or 1) when passing to $^*\varphi$ in $^*\mathcal{U}$. We say that the extension $\mathcal{U} \xrightarrow{*} ^*\mathcal{U}$ is *conservative*. Moreover, \mathcal{U} is not contradictory iff $^*\mathcal{U}$ is (because we can construct models for $^*\mathcal{U}$ starting from \mathcal{U} with ZFC, see [14], or look at [25] 7.38 - 7.40).

Remark 6.1.2. One can define the sets $^*\mathbb{N}, ^*\mathbb{Z}, ^*\mathbb{Q}, ^*\mathbb{R}, ^*\mathbb{C}$ of the non-standard number sets. In particular, in $^*\mathbb{R}$ one gets the notions of infinitesimal, unlimited, infinite etc. numbers. We also can get further proprieties of non-standard numbers. See [14], or look at 7.28 from [25].

6.1.3. Some properties of $*$ (for more of them, see [14], or look at 7.29 from [25]):

- $a = b$ iff $^*a = ^*b$ so $a \mapsto ^*a$ is injective;
- $a \in B$ iff $^*a \in ^*B$;
- $A \subseteq B$ iff $^*A \subseteq ^*B$;
- $^*(a_1, \dots, a_m) = (^*a_1, \dots, ^*a_m), \forall m$;
- $^*\{a_1, \dots, a_m\} = \{^*a_1, \dots, ^*a_m\}, \forall m$.

Definition 6.1.4. A set $B \in \mathcal{U}'$ is called *standard* if $\exists A \in \mathcal{U}$ with $B = ^*A$, otherwise it is called *non-standard*. A non-standard set $B \in ^*\mathcal{U}$ is called *internal* if $\exists A \in \mathcal{U}$ with $B \in ^*A$ and *external* otherwise.

6.1.5. Some Properties of internal sets. (for more proprieties, examples and further developments, see [14], or look at 7.31 - 7.45 from [25]):

- A, B internal $\Rightarrow A \cap B, A \cup B, A \setminus B, A \times B$ internal;
- the union and intersection of any internal collection of sets are internal: if $\{A_i | i \in I\} \in ^*\mathcal{U}$ and A_i internal for any i , then $\bigcup_{i \in I} A_i$ and $\bigcap_{i \in I} A_i$ are internal;
- if a_1, \dots, a_m are internal, then both $\{a_1, \dots, a_m\}$ and (a_1, \dots, a_m) are internal;
- if $f : A \rightarrow B$ is internal, $a \in \text{dom } f = A$ internal, then $f(a)$ is internal; $C \subseteq A$ internal, then $f^i(C)$ is internal; $D \subset B$ internal, then $f^{-1}(D)$ is internal.

Example 6.1.6.

1. \mathbb{N} is an external set in \mathcal{U}' .
2. $^*(A) := \{^*a | a \in A\}$, A infinite is external (note that $^*(A) \neq ^*A$).

6.2. Non-standard Analysis in SET-type topoi. We start now to achieve our main objective from the mathematical point of view, namely to build a Non-standard Analysis (NSA) in topoi, extending the previous theory from the classical setting (in the topos **SET**) to more general topoi. We will be only interested in building NSA in the exponential topoi of the form **SET**^{cop} (such kind of topoi were also used in Quantum Physics). However, for the moment we will give the general definitions, but we will exemplify the ideas on the **SET**-type topoi (see 5.2.4.).

Remark 6.2.1. Let \mathcal{E} be a topos. In 5.3.8. we recalled the existence of all the logical operations in the space of sections $\text{Hom}_{\mathcal{E}}(1, \Omega)$, such that this space become a *MHA* (see 5.3.2.). Hence, we can interpret the notion of theory (in the sense of the 5.1.7.) in any topos.

Definition 6.2.2. Let \mathcal{E} be a topos, and $X \in \text{Ob}(\mathcal{E})$. Then we can associate to any two morphisms $\alpha \in \text{Hom}_{\mathcal{E}}(1, X)$ and $\beta \in \text{Hom}_{\mathcal{E}}(1, X)$ their direct product $(\alpha, \beta) \in \text{Hom}_{\mathcal{E}}(1, X \times X)$ (1 is (the) final object, so $1 \times 1 = 1$). Then, a *binary relation* \mathcal{R} on X is a set of pairs (α, β) as before. As usually, we

write $\alpha \mathcal{R} \beta$ instead of $(\alpha, \beta) \in \mathcal{R}$. We say that a binary relation on X is *finitely satisfiable* iff for any positive integer n and $\alpha_1, \dots, \alpha_n \in \text{Hom}_{\mathcal{E}}(1, X)$ there is $\beta \in \text{Hom}_{\mathcal{E}}(1, X)$ such that $\alpha_1 \mathcal{R} \beta, \dots, \alpha_n \mathcal{R} \beta$.

Definition 6.2.3. Let \mathcal{E} be a topos. An *enlargement* of \mathcal{E} is a monomorphism $*$: $\mathcal{E} \hookrightarrow^* \mathcal{E}$ in a category **CAT** containing both categories \mathcal{E} and $^* \mathcal{E}$, satisfying :

- 1. $^* \mathcal{E}$ is a topos;
- 2. If $\mathbf{V} : \mathcal{P} \rightarrow \text{Hom}_{\mathcal{E}}(1, \Omega)$ is any valuation (see 5.3.9.) (here \mathcal{P} is the set of sentences in the language $\mathcal{L}_{\mathcal{E}}$, 1 is the final object in \mathcal{E} , and Ω is the subobjects classifier from \mathcal{E}), then $^* \mathbf{V}(^* p) = \mathbf{V}(p)$ for any $p \in \mathcal{P}$ (here $^* \mathbf{V} : ^* \mathcal{P} \rightarrow ^* \text{Hom}_{^* \mathcal{E}}(1, ^* \Omega)$ is the non-standard image of the original map \mathbf{V} , $1 = ^* 1$ is the final object, and $^* \Omega$ is the subobjects classifier from $^* \mathcal{E}$);
- 3. For any $X \in \text{Ob}(\mathcal{E})$ and any finitely satisfiable relation R on X there is $g \in ^* \text{Hom}_{^* \mathcal{E}}(1, ^* X)$ such that $\alpha ^* R g$ for any $\alpha \in \text{Hom}_{\mathcal{E}}(1, X)$ (we say that any finitely satisfiable relation is *globally satisfiable*) (if $R \subseteq \text{Hom}_{\mathcal{E}}(1, X \times X)$ then $^* R \subseteq ^* \text{Hom}_{^* \mathcal{E}}(1, ^* X \times ^* X)$).

Definition 6.2.4. The inequality $^* \mathbf{V}(^* p) \leq \mathbf{V}(p)$ from 2. is called **Standardisation (S)**, the converse inequality is called **Transfer (T)**, and the propriety 3. is called **Idealization (I)**. They generalize the similar proprieties from CL appearing in 6.1., and can be formalized in the appropriate language.

Theorem 6.2.5. For any **SET** - type topos \mathcal{E} (see 5.2.4.) there is a non-standard extension (in the sense of 6.2.3.) $*$: $\mathcal{E} \hookrightarrow^* \mathcal{E}$.

Proof. *Step 1.* Let's consider the topos SET^n having as objects n -uples of sets, and as morphisms n -uples of functions, with the canonical compositions and identities, defined component-wise. At this step we will build a non-standard extension for this particular topos. This will be the topos $^* \text{SET}^n$, having as objects n -uples $(^* A_1, \dots, ^* A_n)$ where (A_1, \dots, A_n) runs through the objects of SET^n , and as morphisms n -uples of internal functions $(^* f_1, \dots, ^* f_n)$, where (f_1, \dots, f_n) runs through the morphisms of SET^n (with $*$ being the usual non-standard extension from 6.1). Due to the propriety of transfer (T) of $*$ (see 6.1) and because of 6.1.3., we get that all the proprieties of SET^n contributing to its structure of topos transfers to $^* \text{SET}^n$. In particular, $\Omega_{^* \text{SET}^n} = ^* \Omega_{\text{SET}^n} = (\{0, 1\}, \dots, \{0, 1\})$ (so both topoi have 2^n truth values).

Then $\text{SET}^n \xhookrightarrow{*} ^* \text{SET}^n$ and this is a *conservative* extension of topoi.

More precisely, one can build a NSA on SET^n by imitating the case **SET**. Namely, in SET^n we *define* a union, intersection, and power set on components, namely :

$$(A_1, \dots, A_n) \cup (B_1, \dots, B_n) := (A_1 \cup B_1, \dots, A_n \cup B_n)$$

$$(A_1, \dots, A_n) \cap (B_1, \dots, B_n) := (A_1 \cap B_1, \dots, A_n \cap B_n)$$

$$\mathcal{P}(A_1, \dots, A_n) := (\mathcal{P}(A_1), \dots, \mathcal{P}(A_n)).$$

Then we can build an Universe $\mathcal{U}(X)$ using the same procedure as in 5.1.12. (here $X = (X_1, \dots, X_n)$). In fact, we get that $\mathcal{U}(X) = (\mathcal{U}(X_1), \dots, \mathcal{U}(X_n))$, where $\mathcal{U}(X_i)$ are Universes as in 5.1.12. We can also build the non-standard extension $\mathcal{U}(X) \xhookrightarrow{*} \mathcal{U}(^* X) = \mathcal{U}((^* X_1, \dots, ^* X_n)) = (\mathcal{U}(^* X_1), \dots, \mathcal{U}(^* X_n))$.

We extend the language to $\mathcal{L}_{\mathcal{U}(X)}$ (5.1.13.) and we obtain that $\mathcal{L}_{\mathcal{U}(X)} = (\mathcal{L}_{\mathcal{U}(X_1)}, \dots, \mathcal{L}_{\mathcal{U}(X_n)})$; this can be further component-wise extended to $\mathcal{L}_{\mathcal{U}(^* X)}$.

With 6.1.4. in mind, one can *define* in SET^n the notions of *standard* and *non-standard* object on components (the standard objects are of the form $(^* X_1, \dots, ^* X_n)$, with X_1, \dots, X_n sets; the non-standard objects have an hierarchy of non-standardness, depending on how many components are

non-standard, and which ones - one can rank them using *the lexicographical order* on n-uples); one can define, for the non-standard objects, the *internal* and the *external* objects, namely an object (X_1, \dots, X_n) is internal iff all the sets X_i are internal; and, (X_1, \dots, X_n) is external iff at least one of the X_i is external (as in the case of the non-standard sets, one gets several degrees of externality, lexicographically ordered). A *sentence* in $\mathcal{U}(X)$ consists of an n-uple of sentences from $\mathcal{U}(X_1), \dots, \mathcal{U}(X_n)$, in this order. The degree of truth of a sentence in $\mathcal{U}(X)$ depends on the number of the true sentences from the components, and on their order, with the lexicographical order on n-uples. The degree of truth of a sentence ϕ in $\mathcal{U}(X)$ is kept in $\mathcal{U}(*X)$ and vice-versa, due to T (transfer) and S (standardisation) from the NSA on **SET**. We got in such a way a conservative extension of the intuitionistic (2^n valued) logic of the topos **SET**ⁿ. The idealisation property (I) from NSA remains unchanged.

Step 2. It is easy to see that **SET**ⁿ = **SET**^{n^{op}}, with **n** from 5.2.3. 2) (note that **n** is self-dual).

Step 3. Cf. 5.2.4. a category of **SET**-type has the form **SET**^{C^{op}}, with \mathcal{C} finite (that is having a finite number of objects and morphisms), so, there is $n \in \mathbb{N}$ such that **n** is a subcategory of \mathcal{C}^{op} ($n = \text{card}(\text{Ob}(\mathcal{C})) = \text{card}(\text{Ob}(\mathcal{C}^{op}))$). So, our **SET**-type category is a subcategory of **SET**ⁿ = **SET**ⁿ. Now, it is not hard to check that the restriction of the monomorphism $*$ from *Step 1* gives a non-standard extension of our **SET**-type topos.

7. Infons, Energons, and Receptons : Mathematical Definitions

This is a concluding section of our study, based on all of the previous work. In 7.1. we define the intuitionistic context, and in section 7.2. we *define* mathematically the infons, receptons, and energons, providing some examples of receptons.

7.1. The intuitionistic context.

Definition 7.1.1. A *set* is a class which is an element of another class (see 5.1.1.). Let's denote by \mathcal{M} the class of sets. The *intuitionistic set theory* (*IZF*) is the triplet $(\mathcal{L}_{\mathcal{M}}, IL + IZF, \mathcal{D} = \{MP\})$, where IL are the axioms from 5.3.1., MP is as in 5.1.6., and *IZF* (Intuitionistic Zermelo-Fraenkel) consists in the following axioms (recall that " \in " and " $=$ " are primary relations)

IZF : Axioms of ZF (see 5.1.9. and 5.10 - 5.13 from [25]), where the axiom **Regularity** (**R**) is replaced by the weaker axiom (**Induction**):

$$\forall x((\forall y \in x \wedge \phi(y)) \rightarrow \phi(x)) \rightarrow \forall x\phi(x), \text{ for every formula } \phi.$$

Note that this in setting the double negation, de Morgan's relations, and tertium non datum, do not hold.

Definition 7.1.2. An *Intuitionistic Theory* is an usual theory $\mathcal{T} = (\mathcal{L}, \mathcal{A}, \mathcal{D})$ (see 5.1.7.) in an intuitionistic context, so assuming that \mathcal{A} contains the axioms IL and IZF from before, and that $\mathcal{D} = \{MP\}$ (see 5.1.6.). As in 5.1.7., we *assume*, by definition, that a theory *has at least one model*.

Definition 7.1.3. Using the same notations as in 6.1.1., but with *IZF* from 7.1.1. for intuitionistic set theory, we denote by $\text{IIST} = \text{IZF} + IL + I + S + T$, with IL from 5.3.1., and I, S, T as in 6.2.4. As in 6.1.1. we *define* the *Theory of Intuitionistic Non-standard Extensions*, replacing IST by IIST , and taking only $\mathcal{D} = \{MP\}$ from 5.1.6. The propositional calculus of this theory is a *conservative* extension of the

intuitionistic logic (that is by T and S one conserve the truth values).

7.2. Infons, Receptons, Energons.

Definition 7.2.1. We call a *generalized infon* a Theory $\mathcal{I} = (\mathcal{L}, \mathcal{A}, \mathcal{D})$ in the context of IIST. We call *infon* the collection of entities of the previous form, whose category of models form a non-standard enlargements of a topos of the form $\mathbf{SET}^{\mathcal{C}^{op}}$, where \mathcal{C} is any category (see Section 5. also). We call *preliminary defined infon* the infon whose associated category is a non-standard enlargement of a topos of \mathbf{SET} -type (see 5.2.4.).

Definition 7.2.2. We call a *generalized repton* the category of models of a generalized infon. We call *repton* any non-standard enlargement of a topos of exponential type - $\mathbf{SET}^{\mathcal{C}^{op}}$, where \mathcal{C} is any category (see Section 5. also). We call *preliminary defined repton* any non-standard enlargement of a topos of \mathbf{SET} -type (see 5.2.4.).

We recall in the context that the logic from topoi is intuitionistic, and its non-standard enlargement is a conservative extension (see Sections 5. and 6.), so the infon and the repton are compatible entities, representing the two faces of the same entity.

Remark-Definition 7.2.3. An *energon* is also generalized, normal and preliminary, as before. It is partially infon (when dealing with theories related to potential energy) and partially repton (when dealing with the kinetic, caloric, electromagnetic actual energies), see also Section 3.

Examples 7.2.4. (of preliminary defined receptons) 1). By definition, any non-standard enlargement of a \mathbf{SET} -type topos is a repton. Particular receptons are represented by the enlargement of the graph-type topos $\mathbf{SET}^{n\text{-}\mathcal{G}^{op}}$, or by the enlargement of a geometric topos (see 5.2.6. and 5.2.7.).

2). The Nicolas Bourbaki group of prominent mathematicians from France considered that the fundamental structures in mathematics are (both in the language of theories and of categories) the algebraic structures, topological structures, and order structures, all the others (like the differential ones, for example) being combinations between them. So, in order to apply Mathematics in various arias, one needs to consider collections of such structures, communicating between them. This means that we need to consider various theories and categories together. In the case of categories, the structures are collected in categories, and the communication between them is done with the help of the functors. This means that, in fact, one needs to work with categories of type \mathbf{CAT} (see 5.1.21.), and, as a consequence, with appropriate infons and receptons. This means that an important family of receptons will have the form $\mathbf{SET}^{\mathbf{CAT}^{op}}$ and similarly for the corresponding theories. For example, in Multiversal Quantum Physics several mathematical structures appearing in the usual Quantum Physics were put together in such kind of topoi, such as Hilbert spaces with compact self adjoint operators, von Neumann algebras, and others (see [12]). However, when studying the human and global brain, is necessary to enlarge the things to the non-standard environment, due to the role played by the subconsciousness (see [26], [25]).

8. Conclusions and Further Considerations

Concluding, in this paper we get three kinds of contributions. One is related to pure mathematics by constructing non-standard analysis in the \mathbf{SET} -type topoi (Theorem 6.2.5.). Another one is the presentation of theories from Physics, Neuroscience, Cybernetics focused on the importance and

appearance of the Infons, Energons, Receptons: how they should look like and which is their usefulness (Sections 2.,3.,4.). And, finally, the interpretation of some mathematical theories (Sections 5.,6.) in terms of *infons* and *receptons*, in section 7., compatible with the sections 2.,3.,4.

We will continue our work with part II, where we will build non-standard analysis in general exponential topoi, with applications to infons and receptons in their natural form. Then, these notions should be used in concrete problems of Physics, Neuroscience, Cybernetics, Artificial Intelligence, Economics,... In particular, we will study the (quantum)neural networks and (quantum) Turing machines in the context of topoi, related to the interplay brain/mind (genetic/epigenetic) and in connection with the global brain.

8.1. Example. We end this paper noting that the theory IIST from Section 7. (ZF from Section 5. in the classical case) represents an Infon, containing the empty set. From it (so, from nothingness), one built all the mathematics, by receiving the theory through various Receptons, parts of the Global Brain. And by the Tegmark's Axiom for Multiverses of rank 4 (see 3.1) all the physical entities progressively appear, through Consciousness.

Acknowledgement. The authors of this paper had fruitful scientific discussions with Prof. Leon Zăgrean (Faculty of General Medicine, Bucharest) and Dr. Florin Nichita (Simion Stoilow Institute of Mathematics of the Romanian Academy).
