ABSTRACT

Keywords:

Coronavirus
Infodemiology
COVID-19 infodemic
Collective perceptual bias
Collective behavioral propensities
Psychological Typhoon Eye Effect

Less aligned emphasis has been given to the COVID-19 infodemic coordinating with the COVID-19 outbreak. Global profusion of tangled monikers and hashtags has found their ways in daily communication and contributed to backlash against Chinese. Official naming efforts against infodemic should be meet with a fair share of identification. Based on brief critical reviews on previous multifarious naming practices, we punctuate heuristic introspection in scientific conventions and sociocultural paradigms. Infodemiological analysis promises to articulate that people around the globe are divided in their favor stigmatized monikers in the public and scientific communities because of perceptual bias. There is no positive correlation between the degree of infection in their territories and collective perceptual bias to COVID-19. The official portfolio “COVID-19” and “SARS-CoV-2” has not become *de facto* standard usages, but full-fledged official names are expected to duly contribute to the resilience of negative perceptual bias and collective behavioral propensities.

1. Introduction

On the occasion of the Chinese Lunar New Year of 2020, the 2019 novel coronavirus disease (now known as COVID-19¹) was first reported from Wuhan City of China, home to 11 million people. With the advent of the COVID-19 epidemic, massive infodemic has cast a huge shadow over the epidemic, not merely in the societal sphere, but on the Internet. However, hitherto the infodemic rarely appears in publications to meet with a fair share of identification, and even its unique risk has only been flirted with. For the underrepresented minority case in academia^{2,3}, the “2019-nCoV infodemic” (hereinafter, COVID-19 infodemic) is duly credited with the remarks “the high demand for timely and trustworthy information about 2019-nCoV”.

On one hand, global profusion of running news often inscribe fear, rumors and prejudice into tangled hashtags and monikers. Those monikers and morbid contents always team up with each other in the epicenter of COVID-19 infodemic, wherein one sheds light on the infectivity of the other. The past few weeks has witnessed an explosive growth of stigmatized monikers, which have found their ways in daily communication and contributed to backlash against Chinese.

On the other hand, no learned name, no fighting flag. There is concern that an appropriate nomenclature should be duly assigned to the newly identified coronavirus and caused respiratory tract disease in humans, which has potential public health impact. So far, there is not a universally accepted name yet, either for academic-industrial usage or consistency with international virus taxonomy.

To address such pressing issues, we orchestrate rich metadata available to unfold the picture of the COVID-19 epidemic and COVID-19 infodemic in this infodemiological study.

2. Materials and methods

2.1. Materials

As of 29 February 2020, COVID-19 has spread to 60 countries and territories. Of these, the World Health Organization (WHO) published the number of cumulative cases in 54 Member States on 29 February 2020, as well as Hong Kong, Macao and Taiwan (<https://www.who.int/emergencies/diseases/novel-coronavirus-2019/situation-reports>). We retrieved from the cumulative cases of three non-member states – Iceland, Azerbaijan and Monaco – from their official websites. The corresponding total populations of 2019 comes from United Nations (Department of Economic and Social Affairs, Population Division (2019). World Population Prospects 2019. Rev. 1.).

Moreover, metadata from three information sources, electronic books corpus (Google Books Ngram Corpus (GBNC)), journals (Web of Science (WoS) and PubMed) and the Internet (Google Trends Index (GTI)), will be retrieved and orchestrated to facilitate subsequent analysis. GBNC is a unique linguistic landscape that benefits from centuries of development of rich grammatical and lexical resources as well as cultural contexts⁴. WoS and PubMed are learned publications databases with rich structural meta-data. GTI is knowledge dissemination metrics for query incidence of relevant keywords and phrases. The dynamic spatiotemporal patterns of GTI are faith mirrors of demographic perceptions and collective behavioral propensities.

2.2. Methods

Infodemiology is a science portfolio of information science and epidemiology to address the pressing concerns for public health and policy decisions^{5,6}. Under the umbrella of infodemiological scenarios, meta-analysis on diachronic discourses of pertinent keywords and phrases promises to articulate the unfolding chronological picture since their debutants on a historical time scale⁷. For examples, the earliest usage track-down of “coronavirus” and “coronaviruses” could provide an insightful and compelling argument for rigorous historical story, and finally help us penetrate to the essence of reality. Diachronic discourse of “coronavirus”, “coronaviruses”, “Coronaviridae” and “Nidovirales” in English corpus could reflect the historical milestones and the status quo in the field of human coronaviruses research. In current COVID infodemic, stigmatized monikers are ideal indicators of negative bias, and GTI is employed to determine their populational consumption across various regions over time to characterize collective perceptual bias.

3. Results

3.1. Unfolding history: coronavirus and human coronaviruses

Before discussion of COVID-19 epidemic and COVID-19 infodemic, it is necessary to take a glimpse into the history of scientific taxonomy and nomenclature of emerging virus and infectious disease. In 1966, an International Committee on Nomenclature of Viruses (ICNV) was established with the mission of introducing some degree of order and consistency into the naming of viruses. In 1973, the ICNV became the International Committee on Virus Taxonomy (ICTV), a global authority on the designation and naming of viruses. Another international authoritative body, WHO is responsible for naming new human infectious diseases.

Fig. 1. Diachronic discourse of “coronavirus”, “coronaviruses”, “Coronaviridae” and “Nidovirales” in English corpus from 1963 to 2008. GBNC facsimiles the word frequency of “coronavirus”, “coronaviruses”, “Coronaviridae” and “Nidovirales” in English corpus from 1963 to 2008, respectively. After the initial description of coronaviruses in 1968⁸, there was a mild increase in the numbers of printed books dealing with them, followed by several peaks, after several human coronavirus epidemics: SARS-CoV in 2002–2003, HCoV-NL63 in 2004 and HCoV-HKU1 in 2005. In 1971, “coronaviruses” was officially approved by ICNV^{9,10}. The terms “Coronaviridae”, “Nidovirales” and “Coronavirinae” were officially approved by ICTV in 1975, 1996, 2009, respectively.

However, as an earlier nomenclature practice, the naming history of coronaviruses (CoV) is always misjudged in scientific community (**Figure 1**). In retrospect, on 16 November 1968, eight distinguished virologists proposed the term “coronaviruses” in a brief annotation of *Nature*⁸. In fact, unsung virologist Anthony Peter Waterson (1923 – 1983) and his colleagues should be credited with the coinage of the neologism “coronavirus”^{11,12} [*Personal communication with Prof. Kenneth McIntosh, the only survivor of the authors of the annotation in Nature that proposed this name*⁸]. In humans, there are 7 spectrums of human coronaviruses (HCoVs) known to cause the common cold as well as more severe respiratory disease. Of those, human coronaviruses HCoV-229E, HCoV-NL63, HCoV-OC43 and HCoV-HKU1 are routinely responsible for mild respiratory illnesses

like the common cold but can cause severe infections in immunocompromised individuals. But three members have caused deadly outbreaks: SARS-CoV, MERS-CoV, and the newly identified coronaviruses (now known as SARS-CoV-2¹³).

The diachronic discourse of “coronavirus” and “coronaviruses” in English corpus from 1960 to 2008 unveils that there was a mild increase in the numbers of printed books dealing with them after the initial description of coronaviruses in 1968. Then, each human coronavirus epidemic – SARS-CoV in 2002-2003, HCoV-NL63 in 2004 and HCoV-HKU1 in 2005 – leads to a new wave of hot research (**Figure 1**).

Further, meta-analysis results of WoS and PubMed indicate that known knowledge still remains off-limit in the field of combating emerging HCoVs (**Figure 2**). SARS-CoV-2 is the seventh identified coronavirus that can cause diseases of the respiratory tract via human-to-human transmission. It caused mysterious pneumonia outbreak is spreading far more quickly than the SARS-CoV and MERS-CoV diseases^{1,14,15}, although the epicenter of the outbreak was locked down to curb the pandemic spread. Presently, its clinical severity is yet to be determined, although many fatal cases have occurred. In sum, much remains unclear about the pandemics caused by HCoVs.

Fig. 2. Number of publications with “coronavirus” in Web of Science and PubMed. Coronaviruses are positive-sense single-stranded RNA viruses found in a wide variety of animals, as well as in humans. Seven strains of respiratory coronaviruses known to infect human-to-human: HCoV-OC43 (1965), HCoV-229E (1966), SARS-CoV (2002), HCoV-NL63 (2004), HCoV-HKU1 (2005), MERS-CoV (2012) and SARS-CoV-2 (2019). WHO declared the 2019-nCoV outbreak a public health emergency of international concern (PHEIC) on 30 January 2020. This is the 6th time WHO has declared a PHEIC since the International Health Regulations (IHR) came into force in 2005. Before that, there have been five global health emergencies since such declaration was formalized: swine flu (2009), polio (2014), Ebola (2014 then again in 2019), and Zika (2016).

3.2. Does a virus’ name really matter?

In fact, an ‘inappropriate’ official nomenclature might contribute to infodemic unconsciously. In recent years, humans have witnessed several outbreaks of infectious diseases caused by viruses, with common names given by stakeholders. Each round of naming practice is not always successful. As a case in point, some strongly-held but flawed names such as “Middle Eastern Respiratory Syndrome”¹⁶ and “Swine flu” were accused of unintentional social impacts and negative economic by stigmatizing certain industries or communities (**Figure 2**). “Swine flu,” an influenza strain known to have originated in pigs, resulted in causing great financial damage to farmers, despite there being no evidence that it could be spread via pork consumption. Since these incidents, in May 2015, WHO released some naming conventions for the naming of new human diseases¹⁷.

Unfortunately, accompanying with the COVID-19 epidemic outbreak, another massive infodemic spread virally over the world. Previous evidence suggests that the Internet, by its very nature, could amplify and relay such infodemic swiftly worldwide, furtherly cause global panic and worsen stigmatization against people in the epicenter of outbreak^{18,19}. Much worse in current infodemic, Corona beer is being slashed by the name’s similarity to the deadly coronavirus. In fact, the Mexican brand originated back in 1925

before the first strain of coronavirus was discovered and named, and nothing to do with coronavirus or virus. To address such challenge, WHO declared this infodemic as the “2019-nCoV infodemic” on 2 February².

Can we learn from history? To find the answer, we examine the popularity of top queries of current coronavirus epidemic via the Google Trends Index (**Figure 3**). Those dynamic shares are faithful indicators of collective behaviours across various regions over time. The findings reveal that the 2019 novel coronavirus is thought to have originated in China, which led to it being frequently named “Chinese coronavirus”, “China coronavirus” or “Wuhan coronavirus”. Our survey pinpoint that those stigmatized names might have contributed to recent backlash against Chinese people. Currently, the official portfolio “COVID-19” and “SARS-CoV-2” has not become dominant that it appears to be *de facto* standard usages. People around the globe are divided in their own options on the Internet and in daily communications.

Fig. 3. Illustration on the top query volumes of the 2019 novel coronavirus in infodemic scenario. The Google Trends facsimiles the popularity of “SARS-CoV-2” (gold), “COVID-19” (green), “2019-nCoV” (blue), “Novel Coronavirus Pneumonia” (grey), “novel pneumonia” (cyan), “novel coronavirus” (magenta), “Wuhan pneumonia” (red), “Wuhan coronavirus” (indigo), “China coronavirus” (brown), “China pneumonia” (orange) and “Chinese coronavirus” (maroon) from 30 January 2019 to 29 February 2020, respectively. Comparatively, some stigmatized monikers enjoy high frequencies of collective consumption. The portfolio of full-fledged official names would be beneficial to overdue correctives to such stigmatization. Notably, substantial pattern shifts are observed after the announcements of “2019-nCoV” and “COVID-19”, while “SARS-CoV-2” had failed to keep abreast of “COVID-19”.

3.3. Collective perceptual bias to COVID-19 in the public

As of now, multifarious stigmatized monikers have become dominant in the public, rather than the official portfolio. To further examine the demographical perceptions of collective behavioral propensities in current infodemic, we characterize the relationship between geographical interest of stigmatized monikers and the cumulative rate of the 58 countries and territories, in which confirmed cases of COVID-19 acute respiratory disease has been reported. The results clearly unveil that people in Egypt, Greece, New Zealand, United Kingdom, United States, Canada, Finland, Russia, Philippines, Denmark, Vietnam, Nepal and Mexico would prefer to use stigmatized monikers against Chinese, in comparison with other counterparts (**Figure 4**).

To characterize the patterns behind such collective perceptual bias, we further scrutinize geographical interest of stigmatized monikers against Chinese in 13 typical territories with low cumulative rates over time (**Figure 5**). As co-occurrence perceptual phenomena, the substantial illustration could corroborate that people have enjoyed stigmatized monikers with very high frequencies in these typical territories after 16 January 2020. People has negative perceptual bias in the perception of natural origin of COVID-19 in these regions. Moreover, the prognostic significance of our findings is that such approach is excepted to determine the tipping point of psychological typhoon eye effect in the near future.

Fig. 4. Four-quadrant diagram of the relationship between geographical interest of stigmatized monikers and cumulative rate. As of 29 February 2020, up to 60 countries and territories has reported confirmed cases of COVID-19 acute respiratory disease, including Taiwan, Iceland, Azerbaijan and Monaco. There are no metadata available for San Marino and Monaco in Google Trends, and geographical interest of stigmatized monikers against Chinese in other 58 territories was normalized by median volume for comparing each other. The cumulative rate is the ratio of the number of confirmed cases to the total populations in the countries or territories.

Fig. 5. Dynamic interest of stigmatized monikers against Chinese in typical territories with low cumulative rates. This illustration unveils the geographical interest of stigmatized monikers in 13 typical territories – Egypt, Greece, New Zealand, United Kingdom, United States, Canada, Finland, Russia, Philippines, Denmark, Vietnam, Nepal and Mexico – between 1 January 2020 and 26 February 2020. The median volumes of the corresponding search queries facsimile the trend of collective behavioral propensities over time. Comparatively, some stigmatized monikers against Chinese have been enjoyed with very high frequencies after 16 January. The substantial pattern of high consistent curve indicates that negative perceptual bias is observed in the perception of natural origin of COVID-19 in the public.

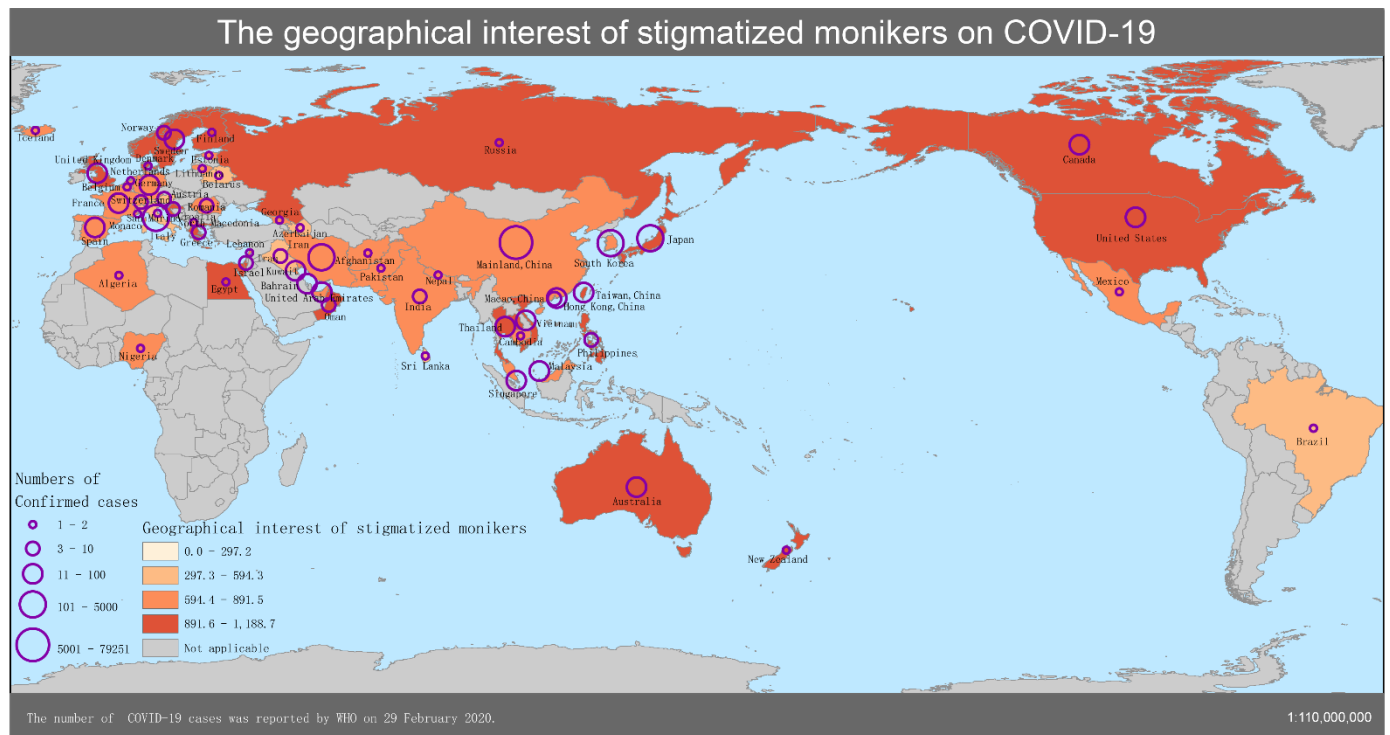

Fig. 6. Geographical map of the COVID-19 infodemic (29 February 2020). Clearly, substantial pattern is also observed in the geographical map of 58 countries and territories with low cumulative rates and negative perceptual bias in the perception of natural origin of COVID-19 in the public.

People hold negative perceptual bias in the perception of natural origin of COVID-19 in the 58 countries and territories with low cumulative rates (Figure 6). In sociocultural setting with relatively complex dimensions beyond geographical structure, this approach of panoramic map empowers us to better understand the prevalence and severity of the COVID-19 infodemic throughout the regions comparatively. This remind us that policy-makers should learn from best practice in the reduction of deliberate infodemic risks, with the pull of go-to resources for knowledge and expertise into academic sphere, as well as in the public.

What's the plausible reasons behind such collective perceptual bias? Demographically, according to Pew Research Center's latest Global Attitudes survey²⁰, a median of 40% in the surveyed countries have a have a positive view of China, compared with a median of 41% who have an unfavorable opinion. However, recognizing COVID-19 acute respiratory disease with potential public health impact, people are easily impressed emotionally by distorted news from the media and neighbor individuals. When the emerging cases reported in their country, the infodemic around its origins flew to and fro and nothing seemed certain or obviously right. This remind us that the army of authoritative organizations should work together with each other and cultivate a well-trained cadre of professionals to mediate infodemic risks.

Notably, from the beginning of COVID-19 epidemic, people in most Asia-Pacific countries, "where many more name China as a top threat"²⁰, prioritize relations with China to jointly fight the COVID epidemic, rather than discrimination against China. Conversely, the underrepresented minority cases, some individuals and media have been committed for slashing China image to the bone by morbid views, such as conspiracy theories of non-natural origin of COVID-19²¹, made-in-China coronavirus, "China is the real Sick Man of Asia", China's Chernobyl moment, etc. Undoubtedly, such ridiculous voices do nothing but create fear, rumors, and prejudice against Chinese, and they have been levied harsh criticism overwhelmingly. On 8 February, the *Lancet* published a statement in solidarity with Chinese professionals in combating the novel coronavirus outbreak and called upon fighting against the army of infodemics^{21,22}. Later, more and more public health scientists have endorsed this statement.

3.4. Collective perceptual bias to COVID-19 in scientific community

Since multifarious stigmatized monikers have become dominant in the public, what's about in scientific sphere? It is critical that having individuals who are well versed in naming conventions for new viruses and pathogenic diseases and collaborate directly with researchers on a regular basis. Unfortunately, prior to generally accepted names for the 2019 novel coronavirus and pathogenic disease, debate on interim solutions has been going on (Table 1).

*Note: As of 26 February 2020, the articles have been retrieved from the PubMed.

On 12 January 2020, WHO provisionally named the 2019 novel coronavirus disease “2019-nCoV”. Later, an emergency ICD-10 code of U07.1 is assigned to the disease diagnosis of 2019-nCoV by the International Classification of Diseases (ICD).

On 7 February 2020, China’s National Health Commission (CNHC) decided to temporarily call the disease “Novel Coronavirus Pneumonia” or “NCP”. This official name has invoked intensive arguments outside as well as inside the scientific community. Firstly, Chinese scientists are divided on that official name. Supporters say the descriptive name follows typical classification practices, whereas opponents claim that it could be easily misunderstood and abused to cause unnecessary fears. Secondly, the word ‘novel’ is confusing in the way that neither the disease nor the host range can be used to reliably determine the virus novelty. Arguably, high mutation and gene recombination rates make this type of virus ideal for pathogen evolution. Once viral mutation happened, it won’t be “novel” any more.

Before that, the 2019 novel coronavirus was designated as “WH-Human-1 coronavirus” or “Wuhan-Human-1 coronavirus” by a group of scientists in *Nature* on 3 February²³. In the same vein, on 11 February, another name “HARS-CoV”, with ‘Han’ standing for ‘Wuhan in Chinese’, was proposed in *The Lancet*²⁴. Obviously, such practices are against the naming principles of WHO²⁵ – geographic locations should be avoided in disease names, and the name should be short and easy to pronounce. Such names might provoke unintended negative impacts by stigmatizing Wuhan citizens and even Chinese people. Those flawed notions take hold should be duly corrected, as well as other similar paradigms (**Table 1**).

In response to such concerns, on 11 February, WHO officially renamed “2019-nCoV” as “COVID-19”, with ‘CO’ meaning ‘corona’, ‘VI’ for ‘virus’, ‘D’ for ‘disease’, and ‘19’ referring to 2019. This generic descriptive reassignment offers an overdue corrective to those strongly-held but flawed notions, with the hope of minimizing stigma. Coinciding with the WHO’s latest announcement, in a bioRxiv preprint¹³, a new name “Severe Acute Respiratory Syndrome coronavirus 2” or “SARS-CoV-2” was penned by the Coronavirus Study Group of the International Committee on Taxonomy of Viruses (ICTV-CSG) on the same day. ICTV-CSG explains that this designation highlights the new strain’s similarity to the SARS-CoV. It is unclear whether the ICTV will take this suggestion into consideration.

In the real dilemma, “SARS-CoV-2” is not a nomenclature endorsed by WHO and some prominent virologists yet^{26,27}. Outside the academic-industrial sphere, people also argued against this official name. Although “SARS-CoV-2” seems to be natural for ICTV-CSG to add a numeral ‘2’ behind “SARS-CoV” to signify their relation, many prominent scientists scramble to refute the latest claim. To the untrained eye, the hasty designation may mislead the public to perceive a severer strain virus as a direct descendant of SARS-CoV, rather than a close affinity for the causative agent of China’s another major viral outbreak in 2002-03. Before that, on 5 February, Prof. Shibo Jiang and his colleagues proposed another name, “Pneumonia Acute Respiratory Syndrome Coronavirus” or “PARS-CoV” in *Cellular & Molecular Immunology*²⁸. In the same token, this assignment also intends to retain equivalent terminology of SARS-CoV.

In fact, the looming worry is that the public are susceptible to SARS-CoV¹⁸, which evokes the memory of higher case fatality ratio. On 9 February, Chen Huan-chun, Chinese academician and virologist, made a public apology for mistakenly saying 2019-nCoV is SARS-CoV, which had stung a sensitive nerve and aroused great consternation in the Chinese public.

Layered on top of mediate infodemic risks, making informed and judicious choice is a catch-22 for each authoritative body. It is necessary to punctuate heuristic cautions and continuous introspection of previous multifarious names^{16,18,25,26}, which is a bedrock of such scientific efforts. Recently, global profusion of squab candidates has been discussed inside the scientific community, as well as on social media. For example, HCoV-19 (Human coronavirus 2019)²⁷; TARS-CoV²⁹ and CARS-CoV, with ‘ARS’ standing for ‘acute respiratory syndrome’, ‘T’ for ‘transmissible’, and ‘C’ for ‘contagious’. Whatever merits and demerits, some of them with plausible reasons should be fairly recognized. Before the pull of academic accession, authority should take an open mind to appreciate modest introspections and rededications to such collective efforts. On 22 February, CNHC officially renamed the temporary English name “NCP” as “COVID-19”, with the hope of sitting well with the reference of WHO and further discouraging the use of stigmatized titles³⁰.

4. Conclusions and implication

With an emphasis on infodemiological analysis and meta-analysis on COVID-19 epidemic and COVID-19 infodemic, we scrutinize collective communication behaviors on the Internet and pertinent usages in publications in sociocultural paradigms to uncover some unfolded motivations and consequences. In summary, the conclusions of our findings are as follows:

1. As an earlier nomenclature practice, the neologism “coronavirus” came from the idea of Anthony Peter Waterson and his colleagues. Due to the misjudgments of its debut in textbooks, the history of science and technology might be redefined, which might result in discouraging us to reminisce those unsung pioneers who have inaugurated induction and stimulation of creative inspiration.
2. New round of infodemic exclusively follows each outbreak of human coronavirus epidemic like never-departing shadow, no exception to the COVID-19. The portfolio of full-fledged official viruses and diseases names would duly contribute to the resilience of negative perceptual bias and collective behavioral propensities in infodemic scenario, and further discourage the spread of stigmatization and racial discrimination.
3. People around the globe are divided in their favor stigmatized monikers because of perceptual bias in the public and scientific communities. Perceptual bias in the perception of natural origin of COVID-19 is part of the reason for negative behavioral propensities in specific regions, rather than the degree of infection in their territories.
4. The prognostic significance of above findings is that infodemiological analysis could be expected to provide a hallmark reference to reframe extensible discussions on the approaching tipping point of psychological typhoon eye effect in the COVID-19 infodemic, as well as substantial patterns of the next infodemic.

At this critical moment, an epoch-making name is expected to be scientifically pithy and socially acceptable, with the faith of minimizing unintentional negative impacts on nations, economies and people. This is a positivist doctrine, not merely for naming

a virus but for the vitality of science and the promotion of social progress. Obviously, some naming practices have conflicted with such doctrine. Learning lessons of infodemic could surely be seen as a pressing necessity of yielding up some guidelines for the adoption of practical principles intended to enhance the possibility for the lessening of stigmatization and discrimination.

Technically, we now see collaborative efforts as a potential way to help strengthen and standardize ongoing international initiatives of WHO and ICTV. Admittedly, understanding of the way naming rules strengthen and enrich the integrity and quality of naming practices under the umbrella of original mission remains nominal rather than substantial^{16,18,25,26}. For example, as the precaution, the word “novel” was recommended by WHO¹⁷ for “indicating a new pathogen of a previously known type, recognizing that this term will become obsolete if other new pathogens of that type are identified.” However, stakeholders frequently reserve ‘novel’ for striking new type of virus, lest the word lose fundamentally its impact without regular amendments.
