- 11 Abstract: In the manufacturing industry, orders are typically scheduled and
- delivered through batches, and the probability of machine failure under high-load
- operation is high. On this basis, we focus on a single machine batch scheduling
- 14 problem with a maintenance interval (SMBSP-MI). The studied problem is
- expressed by three-field representation as  $1|B, MI| \sum F_i + \mu m$ , and the optimization
- objective is to minimize total flow time and delivery costs. Firstly,  $1|B,MI|\sum F_i +$
- 17  $\mu m$  is proved to be NP-hard by Turing reduction. Secondly, shortest processing
- 18 time (SPT) order is shown the optimal scheduling of SMBSP-MI, and a dynamic
- 19 programming algorithm based on SPT (DPA-SPT) with the time complexity of
- $O(n^3T_1)$  is proposed. A small-scale example is designed to verify the feasibility of
- 21 DPA-SPT. Finally, DPA-SPT is approximated to a fully-polynomial dynamic
- 22 programming approximation algorithm based on SPT (FDPAA-SPT) by intervals
- partitioning technique. The proposed FDPAA-SPT runs in  $O(\frac{n^5}{\epsilon^2})$  time with the
- 24 approximation  $(1 + \varepsilon)$ .

#### 1. Introduction

Single machine scheduling problem is ubiquitous in manufacturing. As of December 2019, the number of small and micro enterprises in China accounted for 82.5% of the national number [1]. Although modern manufacturing has shifted toward intensification and large factories, in terms of quantity, small and micro enterprises still make up a large proportion. Unlike large enterprises that have a large number of machines and assembly lines, in small and micro enterprises,

36 especially micro enterprises, there is only one machine in the workshop production. 37 Due to the large number of machines in large enterprises, accidental machine failure 38 has little impact on the completion of the entire production plan. In 2017, a single 39 machine in the large-scale wafer factory of Magnesium Group failed, and the 40 maintenance of the machine took a lot of time, resulting in a serious lag in 41 production progress. The lag in production progress has led to insufficient capacity 42 of memory products using wafers as raw materials, which has triggered a surge in 43 the prices of related products worldwide. The influence of machine failure on large 44 enterprises is still the same. For small enterprises with only one or a few machines, 45 once one or several machines fail, it will be under a significant negative impact on 46 their production plans. It can be seen that despite the fact that the occurrence of 47 machine failure is a small probability event, once the machine fails, it will have many 48 adverse effects. By reasonably shutting down and inspecting the machine regularly, 49 the probability of machine failure can be greatly reduced.

In the actual production and trading process, the finished products are usually delivered to customers in batches. Based on this fact, many scholars have conducted research in the field of batch scheduling. Ikura etc. [2] studied single machine batch scheduling problem with the goal of minimizing the maximum completion time. An approximate algorithm was proposed, while the effect of this algorithm is not ideal. Chang etc. [3] further studied the same problem and proposed a Simulated Annealing Algorithm (SAA) with better optimization effect. In Chang's paper, Longest processing time (LPT) order was applied to optimize the initial solution of SAA. Lee etc. [4] proposed a pseudo-polynomial time exact algorithm and a complete polynomial time approximate algorithm to minimize total completion time of SMBSP with dynamic job arrivals. Branch and bound algorithm (BBA) is another algorithm that is commonly used to solve single machine batch scheduling problems. For typical case, see reference [4]. In referrence [5], Azizoglu etc. proposed a BBA to minimize total weighted completion time of SMBSP. In addition to the batch singlemachine scheduling problem, research on the single machine scheduling problem with unavailable intervals (SMSP-UI) is also one of the research hotspots. Several researchers have made progress in SMSP-UI. Sanlaville etc. [6] and Ma etc. [7] independently reviewed the research in this field in recent decades. To optimize the total weighted completion time of SMSP-UI, Ma etc. [8] proposed a dynamic programming algorithm (DPA) and a BBA. both runs in pseudo-polynomial time. Although both DPA and BBA are feasible, they are both pseudo-polynomial time algorithms. In addition, Ma etc. [9] proposed a heuristic algorithm based on longest processing time (LPT) order to minimize max completion time of SMSP-UI. Xie etc. [10] designed a heuristic algorithm which runs in polynomial time to optimize delivery time of SMSP-UI with job rejection. Luo etc. [11] studied a mew branch of SMSP-UI, in which the maintenance time is related to workload. An approximate algorithm running in polynomial time was proposed to optimize total weighted completion time.

It is clear from the above literature review, however, despite the in-depth study in the field of SMBSP and SMSPUI, single machine batch scheduling with maintenance intervals (SMBSP-MI) is still a blind spot for research. Since the outbreak of the COVID-19 virus in January 2020, the production capacity of major mask manufacturers worldwide has been unable to meet demand, and a large number of household mask factories have appeared in this context. Most of these small mask factories work independently or independently from each other. Due to the serious shortage of production capacity, mask machines usually need to work at full load or overload, which greatly increases the probability of machine failure. Therefore, it is necessary to carry out regular shutdown and maintenance of the mask machine. This paper studies SMBSP-MI of a single mask machine scheduling environment. First, the mathematical programming model of SMBSP-MI is established, and then the SMBSP-MI is proved to be NP-hard. On this basis, shortest processing time (SPT) order is proved the optimal scheduling rule of SMBSP-MI, and a DPA based on SPT (DPA-SPT) is running in  $O(n^3T_1)$  is proposed. Finally, an approximate method is added to reduce the time complexity of DPA-SPT to polynomial time.

## 2. Problem description

Since the outbreak of the COVID-19 virus in January 2020, the production capacity of major mask manufacturers worldwide has been unable to meet demand, and a large number of household mask factories have appeared in this context. Most of these small mask factories work independently or independently from each other. Due to the serious shortage of production capacity, mask machines usually need to work at full load or overload, which greatly increases the probability of machine failure. Therefore, it is necessary to carry out regular shutdown and maintenance of the mask machine. This paper studies the maintenance scheduling problem in the environment of a masking machine. The problem is described as follows: Mask orders for multiple customers are processed on one mask machine. The factory needs to process n quantities of raw materials into masks. Because different customers have different delivery times, the raw materials are processed in batches. Due to a large number of orders, the mask machine needs high-load work. To reduce and avoid the probability of machine failure due to high-load work and ensure smooth production, the factory regularly shuts down the mask machine for maintenance. To ensure that the delivery schedule is not affected while overhauling, the total process time and delivery cost of mask production are used as evaluation indicators

The mathematical description of SMBSP-MI is: n jobs are processed in batches on single machine. The set of jobs is  $J = \{j_1, j_2, ..., j_n\}$ . Jobs in J is divided into m batches, i.e.,  $B = \{B_1, B_2, ..., B_k, ..., B_m\}$ , where  $B_k$  represents a batch of jobs, and B is the set of all batches. Once a batch of jobs is processed, it is delivered to the customer. The unit batch delivery cost is  $\mu$ . A maintenance interval (MI) is set

4 of 17

- during the machining process, where MI begins at time  $T_1$  and ends at time  $T_2$ . No
- job is allowed to be processed during MI. The goal is to optimize schedule of batches
- and jobs, so that the sum of total flow time  $\sum_{j=1}^{n} F_j$  and delivery cost total  $\mu m$  is
- minimized. SMBSP-MI is expressed by three-field representation as  $1|B,MI|\sum F_i$  +
- 124  $\mu m$ .

133

134

144

148

The mathematical programming model of SMBSP-MI is expressed as follows.

$$\min Z = \sum_{i=1}^{n} F_i + \mu m \tag{1}$$

127 **s.t.** 

$$\sum_{j=1}^{n} F_j = \sum_{k=1}^{m} F_{J_k}$$
 (2)

129 
$$F_{J_k^i} = \begin{cases} F_{J_k^{i-1}} + C_{J_k^i}, & i > 1 \\ F_{J_{k-1}^{last}} + C_{J_k^i}, & i < 1 \end{cases}$$
 (3)

130 
$$C_{J_k^i} = \begin{cases} C_{J_k^{i-1}} + p_{J_k^i} + \gamma (T_2 - T_1), & i > 1 \\ C_{J_{k-1}^{last}} + p_{J_k^i} + \gamma (T_2 - T_1), & i < 1 \end{cases}$$
 (4)

131 
$$\gamma = \begin{cases} 1, C_{J_k^{i-1}} + p_{J_k^i} > T_1 \\ 0, C_{J_k^{i-1}} + p_{J_k^i} < T_1 \end{cases}, or \quad \gamma = \begin{cases} 1, C_{J_{k-1}^{last}} + p_{J_k^i} > T_1 \\ 0, C_{J_{k-1}^{last}} + p_{J_k^i} < T_1 \end{cases}$$
 (5)

132 
$$p_{max} \le T_1 < T_2 \le \tau \sum_{j=1}^n p_j \tag{6}$$

scheduled batch, and  $\mu m$  is total delivery cost. Formula 2 indicates that the total 135 flow time of all jobs is equal to the sum of the flow time of all batches. This formula 136 137 makes it convenient to calculate the total flow time in an efficient way. Formula 3 138 indicates that the flow time of the *i*th job in the *k*th batch is equal to the sum of the flow time of the previous processed job and the completion time of  $J_k^i$ . i=1 means 139 that  $J_k^i$  is the first job to be processed in the kth batch, thus the previous job of  $J_k^i$  is 140  $J_{k-1}^{last}$  i.e. the last job processed in the (k-1)th batch . The previous job of  $J_k^i$  is  $J_k^{i-1}$ 141 while i > 1, respectively. Formula 4 and 5 explains the calculation of  $J_k^i$ 's completion 142 time, where  $\gamma$  is a 0-1 variable to judge whether  $J_k^i$  is allowed to be processed 143

Formula 1 is the objective function, in which  $F_{J_k}$  is flow time of the kth

145  $c_{J_{k-1}^{last}} + p_{J_k^i} < T_1$ ), otherwise it is to be processed after MI. The strong constraint of

before MI. i.e.  $J_k^i$  is allowed to be processed immediately while  $C_{J_k^{i-1}} + p_{J_k^i} < T_1$  (or

- formula 6 ensures that the processing time of any job is not greater than  $T_1$ , and the
- end of MI is not earlier than the sum of the processing time of all jobs.

#### 3. The NP-hard attribute of SMBSP-MI

- If  $\mu$ =0 and |MI| = 0, this problem is reduced to  $1|B|\sum F_i$ , which is proved to be
- NP-hard by Yang [12]. Obviously  $1|B,MI|\sum F_i + \mu m$  is more complicated than
- 152  $1|B|\sum F_i$ , hence is supposed to be an NP-hard problem. In what follows,
- 153  $1|B,MI|\sum F_i + \mu m$  is proved an NP-hard problem by reducing of equal-size
- partition problem [13-15].
- Equal-size partition problem is described as: Given a set I =
- 156  $(a_1, a_2, ..., a_j, ..., a_{2u}), a_j \in \mathbb{N}^*$ , and  $\sum_{j=1}^{2u} a_j = 2M$ . Are there two disjoint subsets
- 157  $I_1$  and  $I_2$ , where  $|I_1| = |I_2|$  and  $\sum_{j \in I_1} a_j = \sum_{j \in I_2} a_j = M$ ?
- 158 **Theorem 1.** SMBSP-MI is an NP-hard problem.
  - **Proof.** The NP-hard attribute of SMBSP-MI is proved by the reduction of the Equal-Size Partition Problem. Let  $M \ge u + 2$ . The Equal-Size Partition Problem is obviously meaningless when M < u + 2, so the situation of M < u + 2 is not considered. An example of equal-size partition problem is established bellow, variables of example see table 1.

Table 1. variables of equal-size partition example

variables	equations
n	n = 2u + 1
$p_{j}$	$p_j = \begin{cases} M + a_j, j = 1, 2, \dots, 2u \\ (u+2)M, j = 2u+1 \end{cases}$
$T_1$	(u+1)M
$T_2$	M3 + (u+1)M
$\mu$	$\mu = (u-1) M^3 + 2(2u^2 + 3u + 1)M$
U (Z threshold)	$U = (3u-1)M^3 + 4(3u^2 + 5u + 2)M$

169

170

171172

173

174

In what follows, we will prove that the equal-size partition problem has a feasible solution, if and only if the constructed example has a solution which does not exceed U. Let the sets  $I_1$  and  $I_1$  be the solutions to Equal-Size Partition Problem. Let collection B represent the set of jobs corresponding to set  $I_1$ , A represent the set of artifacts corresponding to collection  $I_2$ .

Consider a situation where jobs in B are divided into one batch and processed before  $T_1$ , and jobs in A are divided into one batch and processed after  $T_2$ . The objective function is

6 of 17

175 
$$Z = \sum_{j=1}^{n} F_j + 2\mu = u \sum_{j \in B} (M + a_j) + (+1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + \sum_{j \in A - \{u+1\}} (M + a_j) + (-1)(M^3 + (u+1)M + a_j) + (-1)(M^3 + a_j) + (-1$$

176 
$$a_j$$
 +  $(u+2)M$  =  $u(u+1)M + (u+1)(M^3 + 2(u+1)M + (u+2)M) + 2((u-1)M + (u+2)M) + 2(u+1)M + (u+2)M + 2(u+1)M + (u+2)M + 2(u+1)M +$ 

- 177  $1)M^3 + 2(2u^2 + 3u + 1)M) = (3u 1)M^3 + 4(3u^2 + 5u + 2)M$
- In this case the function value is exactly U.
- 179 Conversely, assume that there is a feasible schedule with the objective value not
- exceeding U. Let B and A be the sets of jobs scheduled before  $T_1$  and after  $T_2$ ,
- 181 respectively. Then the following assertions hold:
- 182 1) The (2u + 1)th job is processed after  $T_2$ ;
- 183 2) There are only two batches in this feasible schedule, one batch is processed before  $T_1$  and another batch is processed after  $T_2$ , respectively.
- 185 3) |B| = u, |A| = u + 1;
- 186 4)  $\sum_{j \in B} p_j = M$ .
- The proof of these assertions is as follows:
- 188 1) The (2u + 1)th job is processed after  $T_2$  because  $p_{2u+1} + M^3 > T$ ;
- 189 2) Three possible cases are considered to prove assertion 2.
- 190 Case 1: There is one batch in this schedule, i.e. all jobs are processed after  $T_2$ ,
- 191 and thus

192 
$$\sum_{j=1}^{n} F_j + \mu m = (2u+1)M(M^3 + 3(u+1)M + (u+2)M) + ((u-1)M^3 + 3(u+2)M + (u+2)M + (u+2)$$

193 
$$2(2u^2 + 3u + 1)M) = 3uM^2 + (12u^2 + 20u + 7)M > U,$$

- which contradicts the constraint that  $Z = \sum_{j=1}^{n} F_j + \mu m \le U$ .
- 195 Case 2: Jobs are divided into more than two batches, i.e. there are at least two
- 196 jobs processed after  $T_2$ .

197 
$$\sum_{j=1}^{n} F_j + \mu m > (2u+1)M(M^3 + 3(u+1)M + (u+2)M) + ((u-1)M^3 + 2u+1)M(M^3 + 3(u+1)M + 2u+1)M(M^3 + 2u+1)M$$

198 
$$2(2u^2 + 3u + 1)M) = 3uM^2 + (12u^2 + 20u + 7)M > U$$
,

- which contradicts the constraint that  $Z = \sum_{j=1}^{n} F_j + \mu m \le U$ .
- Case 3: Jobs are divided into two batches and both batches are processed after
- 201  $T_2$ .
- 202  $\sum_{i=1}^{n} F_i + 2\mu U > (2u+1)M^3 + (u+1)M (u+1)(M^3 + 4(u+1)M) =$
- $203 M(uM^2 2u^2 5u 3) > 0$
- which contradicts the constraint that  $Z = \sum_{i=1}^{n} F_i + \mu m \le U$ . The inequality
- 205 holds because  $M \ge u + 2$ .
- 206 3) As shown in table 1,  $T_1=(u+1)M$  and  $p_j>M$ , thus  $|B|\leq u$ . Take the case that  $|A|\geq 207$
- 207 u+1 under consideration. Let  $\sum_{j\in B} p_j = C \le M$  and  $|A| = u+1+\vartheta$ ,  $\vartheta \ge 1$ .

$$\sum_{j=1}^{n} F_j + 2\mu - U = (u - \vartheta) ((u - \vartheta)M) + C + (u + 1 + \vartheta)(M^3 + (u + 1)M + (u + 1)M) + C + (u + 1 + \vartheta)(M^3 + (u + 1)M) + C + (u + 1)M + C + (u + 1)M) + C + (u + 1)M + C + (u + 1)M) + C + (u + 1)M + C +$$

- 209  $\vartheta)M + (2M C) + (u + 2)M) ((u + 1)M^3 + 4(u + 1)^2M) = \vartheta M^3 + (2u\vartheta + 1)^2M$
- $2\vartheta^2 + 6\vartheta + 1)M (2\vartheta + 1)C \ge \vartheta M^3 + (2u\vartheta + 2\vartheta^2 + 6\vartheta + 1)M (2\vartheta + 1)M > 2\vartheta^2 + 6\vartheta + 1$
- 211 0
- which contradicts the constraint that  $Z = \sum_{j=1}^{n} F_j + \mu m \le U$ . Thus  $|A| \le u + 1$ .
- Considering the former assumption that  $|A| \ge u + 1$ , we get |A| = u + 1, and
- |B| = u, respectively.
- 215 4) As shown in the proof of assertion 3, |A| = u + 1, |B| = u. If C < M, then
- 218 2)M)  $((u + 1)M^3 + 4(u + 1)^2M$ ) =  $(4u^2 + 8u + 5)M C 4(u + 1)^2M = M C >$
- 219 0,
- which contradicts the constraint that  $Z = \sum_{j=1}^{n} F_j + \mu m \le U$ . Thus  $C \ge M$ .
- Considering the former assumption that  $C \leq M$ , we get C = M, and  $\sum_{j \in B} p_j = C = M$
- 222 M.

216

- The proof of proposed assertions is completed, Equal-Size Partition Problem has
- a feasible solution. SMBSP-MI is NP-hard.
- 225 **4. DPA-SPT**
- In this section, the Shortest Processing Time (SPT) order [16-19] is proved to be
- 227 the optimal scheduling rule of SMBSP-MI. And a Dynamic Programming Algorithm
- 228 (DPA) based on SPT is proposed after that.
- Theorem 2. SPT order is the optimal scheduling rule of SMBSP-MI.
- 230 **Proof.** Assume that there is an optimal schedule that does not follow SPT order
- 231  $S = (B_1, B_2, \dots, B_k, \dots, B_l, \dots, B_u, MI, B_{u+1}, \dots, B_m),$
- 232 in which  $p_{i \in B_1} > p_{i \in B_2} > ... > p_{i \in B_k} > ... > p_{i \in B_l} > ... > p_{i \in B_u} > p_{i \in B_{u+1}} > ... > p_{i \in B_m}$ . Take  $j_{B_k}^f$ , i.e. the fth
- job of the kth batch, and  $j_{B_l}^g$ , i.e. the gth job of the lth batch with the inequality  $p_{j_{B_k}^f}$
- 234  $p_{j_{B_l}^g}$ . Exchange  $j_{B_k}^f$  and  $j_{B_l}^g$ , i.e.  $j_{B_l}^g \in B_k$  and  $j_{B_k}^f \in B_l$ . A new schedule S' is established.
- The objective Z with s' is increased by  $z_{s'} z_s$ , comparing to it is with S.

$$Z_{S'} - Z_S = -(|B_k| + |B_{k+1}| + \dots + |B_{l-1}|)(p_{j_{B_k}^f} - p_{j_{B_l}^g}) > 0,$$

- 237 which contradicts the assumption that *S* is the optimal schedule of SMBSP-MI, and
- thus  $p_{j_{B_{I}}^{f}} \leq p_{j_{B_{I}}^{g}}$ . S' is the optimal schedule of SMBSP-MI, that is

239 
$$S' = (B_1, B_2, \dots, B_k, \dots, B_l, \dots, B_u, MI, B_{u+1}, \dots, B_m),$$

240 in which  $p_{i \in B_1} \le p_{i \in B_2} \le ... \le p_{i \in B_k} \le ... \le p_{i \in B_l} \le ... \le p_{i \in B_u} \le p_{i \in B_{u+1}} \le ... \le p_{i \in B_m}$ . 241 Note that batches of schedule S' are processed following SPT order, and sequence 242 of jobs in batch does not affect the flow time of this batch. 243 As is known, DPA is an exact algorithm, which implies that any step of DPA 244 meet the best choice. Since SPT is shown the optimal scheduling order of SMBSP-MI, 245 a DPA based on SPT order (DPA-SPT) is established as follows. 246 Since there are *n* jobs in total, DPA-SPT contains n cycles of iterations. Several states are produced while containing the jth into S'. Let  $R_j = (s_i^1, ..., s_i^i, ..., s_i^x)$  be the 247 set of the states produced in the *j*th cycle of iteration, in which  $s_i^i = (l, c_1, c_2, a, t)$  is 248 one of the feasible states. Variables and parameters in  $s_j^i$  are defined as follows: l249 250 denotes finish time of the last job processed before  $T_1$ ;  $c_1$  denotes number of jobs 251 in the last batch processed before  $T_1$ ;  $c_2$  denotes number of jobs in the first batch 252 processed after  $T_2$  (these jobs may be in the same batch with those processed before 253  $T_1$ , if processing of the last batch is interrupt by MI); a denotes number of jobs 254 processed after  $T_2$ ; t denotes the sum of current total flow time and delivery cost. 255 Since DPA select the optimal job in every cycle of iteration, the current optimal schedule of SMBSP-MI before the *j*th iteration is  $S_{j-1} = (1_{best}, 2_{best}, \dots, (j-1)_{best})$ . 256

And by comparing t values of all states produced in the following cycle of iteration, the one with minimal t value is chosen as  $j_{best}$ . And  $j_{best}$  is at one of the possible position on the machine, i.e.  $j_{best}$  is located in the last batch processed before  $T_1$ ;  $j_{best}$  is located in one of other batches processed before  $T_1$ ;  $j_{best}$  is located in the first batch processed after  $T_2$ ;  $j_{best}$  is located in one of other batches processed after  $T_2$ , respectively. The optimal value  $Z_{min}^*$  will be found after all jobs are sequenced, and the optimal schedule of SMBSP-MI will be decided by backtracking, respectively.

The pseudo code of DPA-SPT is as follows.

### **Algorithm 1**: DPA-SPT

```
Input: J, m, \mu, T_1, T_2
```

Output:  $Z_{min}^*$ 

Initialization.

$$R_1 = \{(p_1, 1, 0, 0, p_1 + \mu), (0, 0, 1, 1, T_2 + p_1 + \mu)\};$$

Iteration.

For 
$$j = 2$$
 to  $n$  do

Set 
$$R_i = \emptyset$$
;

```
For (l, c_1, c_2, a, t) \in R_{i-1}
          If l + p_1 \le T_1 and c_1 > 1 then
              s_i = (l + p_i, c_1 + 1, c_2, a, t + l + (c_1 + 1)p_i);
          If l + p_1 \le T_1 then
              s_i = (l + p_i, 1, c_2, a, t + l + p_i + \mu);
          If c_2 > 1 then
              s_i = (l, c_1, c_2 + 1, a + 1, t + T_2 + \sum_{k=1}^{j} p_k - l + c_2 p_i);
          Else then
            s_i = (l, c_1, 1, \alpha + 1, t + T_2 + \sum_{k=1}^{j} p_k - l + \mu).
          End if;
         End for;
     For s_i^1 = (l, c_1, c_2, a, t) \in R_i, s_i^2 = (l, c_1, c_2, a', t') \in R_i
         If t < t' then
            Eliminate s_i^2 from R_i;
         Else then
           Eliminate s_i^1 from R_i;
         End if;
     End for;
   End for;
Optimization. Z_{min}^* = min_{(l,c_1,c_2,a,t) \in R_n}\{t\}.
```

, ,

The optimal schedule is obtained by backtracking.

For any state  $s_j = (l, c_1, c_2, a, t)$ , the upper bound of l is  $T_1$ , the upper bound of  $c_1$  is n, the upper bound of  $c_2$  is (n+1), and the upper bound of j is (n+1). Hence the complexity of DPA-SPT is  $O(n^3T_1)$ , and thus DPA-SPT is a pseudo-polynomial time

exact algorithm.

Although DPA-SPT achieve best solution of small and medium scale problems, it is not feasible for large-scale problems. With the expansion of the problem scale, the complexity of DPA-SPT faces exponential dimension explosion. Taking into account this problem, the use of elimination is the core of approximation to reduce the complexity down to polynomial time. By pruning some bad states and the application of state pruning technology[17], the solution space that the algorithm needs to search is reduced, so as to reduce the complexity. In addition, due to elimination operation, the optimal solution may be missed, hence the improved algorithm is an approximate algorithm. In what follows, a fully-polynomial dynamic programming approximation algorithm based on SPT (FDPAA-SPT) is designed.

- Take two large number L and V, where  $L \le Z^* \le V$ . Take a  $\varepsilon > 0$ , let  $\delta_1 = \frac{L\varepsilon}{2n}$ ,
- 310  $\delta_2 = \frac{T\varepsilon}{2n}$ . Divide [0, V] and  $[0, T_1]$  into  $\left\lceil \frac{V}{\delta_1} \right\rceil$  and  $\left\lceil \frac{T_1}{\delta_2} \right\rceil$  sub intervals, respectively. In
- 311 this way,  $[0, V] \times [0, T_1]$  is divided into  $\left[\frac{V}{\delta_1}\right] \times \left[\frac{T_1}{\delta_2}\right]$  subintervals.
- To get a polynomial-time approximation schedule, the state set  $R_i$  obtained by
- 313 the *j*th iteration of DPA-SPT is pruned. A new set  $R_i^*$  is produced, and  $R_i^*$  satisfies
- 314 the following attribute:
- 315 (1)  $R_j^* \in R_j$ ;
- 316 (2) There is only one  $R_j^*$  in the same subinterval of  $\left[\frac{V}{\delta_1}\right] \times \left[\frac{T_1}{\delta_2}\right]$ ;
- 317 (3) For any eliminated state  $(l, c_1, c_2, a, t)$ , there is a state  $(l', c_1, c_2, a', t') \in R_j^*$  locating in the same subinterval with it.
- The pseudo code of FDPAA-SPT is as follows.

# Algorithm 2: FDPAA-SPT

**Input**: J, m,  $\mu$ ,  $T_1$ ,  $T_2$ , L, V,  $\delta_1$ ,  $\delta_2$ 

Output:  $Z_{min}^*$ 

Initialization.

$$[0, \delta_1), [\delta_1, 2\delta_1), \dots, \left[\left(\left[\frac{V}{\delta_1}\right] - 1\right)\delta_1, V\right) \leftarrow [0, V];$$

$$[0, \delta_2), [\delta_2, 2\delta_2), \dots, \left[\left(\left[\frac{v}{\delta_2}\right] - 1\right)\delta_1, T_1\right) \leftarrow [0, T_1];$$

$$R_1 = \{(p_1, 1, 0, 0, p_1 + \mu), (0, 0, 1, 1, T_2 + p_1 + \mu)\};$$

Iteration.

For 
$$j = 2$$
 to  $n$  do

Set 
$$R_j^* = \emptyset$$
;

```
For (l, c_1, c_2, a, t) \in R_{i-1}^*
          If l + p_1 \le T_1 and c_1 > 1 then
              s_i^* = (l + p_i, c_1 + 1, c_2, a, t + l + (c_1 + 1)p_i);
          If l + p_1 \le T_1 then
              s_i^* = (l + p_i, 1, c_2, a, t + l + p_i + \mu);
          If c_2 > 1 then
              s_i^* = (l, c_1, c_2 + 1, a + 1, t + T_2 + \sum_{k=1}^{j} p_k - l + c_2 p_i);
          Else then
            s_i^* = (l, c_1, 1, \alpha + 1, t + T_2 + \sum_{k=1}^{j} p_k - l + \mu).

        Else
          Keep s_i^*;
     End for;
     For s_i^{*1} = (l, c_1, c_2, a, t) \in R_i^*, s_i^{*2} = (l', c_1, c_2, a', t') \in R_i^*
         If l < l' and t < t' then
            Eliminate s_i^{*2} from R_i^*;
         Else then
           Eliminate s_i^{*1} from R_i^*;
        End if;
     End for;
   End for;
Optimization. Z_{min}^* = min_{(l,c_1,c_2,a,t) \in R_n^*} \{t\}.
The optimal schedule is obtained by backtracking.
```

13 of 17

- 322 The approximation process of FDPAA-SPT reduces its complexity to 1, and the gap
- between the optimization solution and the approximate solution of FDPAA-SPT is
- 324 2. In what follows, the two conclusions are proved.
- 325 **Theorem 3.** For any eliminated state  $s_j^i = (l, c_1, c_2, a, t) \in R_j$ , there exists a state
- 326  $s_i^* = (l', c_1, c_2, a', t') \in R_i^*$ , where l < l' and  $t < t + n\delta + na\delta$ .
- 327 **Proof.** Mathematical induction is used to prove theorem 3. When n = 1,  $s_1 =$
- 328  $(l, c_1, c_2, a, t) = s_i^*$ , theorem 3 holds. Assume that theorem 3 holds while n = j 1,
- 329 i.e. for any eliminated state  $s_{j-1}^i = (l, c_1, c_2, a, t) \in R_{j-1}$ , there exists a state  $s_{j-1}^* = (l, c_1, c_2, a, t) \in R_{j-1}$
- 330  $(l', c_1, c_2, a', t') \in R_{j-1}^*$ , where l < l' and  $t < t + (j-1)\delta + (j-1)a\delta$ . When it
- comes to n = j, considering the diversity of states in  $R_j$ ,  $s_j$  may be produced from
- 332 one of the following former cases:
- 333 Case 1:  $s_{j-1} = (l p_j, c_1 1, c_2, a, t l c_1 p_j) \in R_{j-1}$ ;
- 334 Case 2:  $s_{j-1} = (l p_j, x, c_1, c_2, t l p_j \mu) \in R_{j-1}, \ 0 \le x \le n c_1 1;$
- 335 Case 3:  $s_{j-1} = (l, c_1, c_2 1, a 1, t + l \sum_{k=1}^{j} p_k (c_1 1)p_j) \in R_{j-1};$
- 336 Case 4:  $s_{j-1} = (l, c_1, y, a 1, t T_2 + l \sum_{k=1}^{j} p_k \mu) \in R_{j-1};$
- In what follows, we prove that no matter how  $s_i$  is produced, it satisfies the
- assumption of theorem 3.
- In case 1, there is a state  $s_{j-1}^* = (l', c_1 1, c_2, a', t') \in R_{j-1}^*$  satisfying inequalities
- 340  $l' < l p_j$  and  $t' < t l c_1 p_j + (j-1)\delta_1 + (j-1)a\delta_2$ . This judgment is clear due
- 341 to the assumption of n = j 1. And in this case, inequality  $l' + p_j \le l \le T_1$  holds.
- 342 By iteration phase of FDPAA-SPT,  $s_j = (l' + p_j, c_1, c_2, a, t' + l' + ac_1) \in R_j$  is
- 343 produced, and inequalities  $l' < l p_j$  and  $t' < t l c_1 p_j + (j-1)\delta_1 + (j-1)\delta_1$
- 344 1) $a\delta_2$  holds. According to elimination phase of FDPAA-SPT, there is a state  $s_i^* =$
- 345  $(l'', 1, c_2, a'', t'') \in R_j^*$  locating in the same subinterval of  $R_j$  with  $s_j$ . And  $l'' \le l' +$

346 
$$p_j \le l$$
 holds. Hence  $t'' \le t' + l' + c_1 p_j + \delta_1 \le t - l - c_1 p_j + (j-1)\delta_1 + (j-1)\delta_1$ 

347 1)
$$a\delta_2 + l' + c_1p_j + \delta_1 < t + j\delta_1 + ja\delta_2$$
.

In case 2, there is state 
$$s_{j-1}^* = (l', c_1 - 1, c_2, a', t') \in R_{j-1}^*$$
 satisfying inequalities

349 
$$l' < l - p_j$$
 and  $t' < t - l - p_j - \mu + (j - 1)\delta_1 + (j - 1)a\delta_2$ . By iteration phase of

350 FDPAA-SPT, 
$$s_j = (l' + p_j, 1, c_2, a, t' + l' + \mu) \in R_j$$
 is produced. According to

351 elimination phase of FDPAA-SPT, there is a state 
$$s_i^* = (l'', 1, c_2, a'', t'') \in R_i^*$$

locating in the same subinterval of 
$$R_j$$
 with  $s_j$ . And  $l'' \le l' + p_j \le l$  holds. Hence

353 
$$t'' \le t' + l' + \mu + \delta_1 \le t - l - \mu + (j-1)\delta_1 + (j-1)a\delta_2 + l' + \mu + \delta_1 < t + j\delta_1 + k$$

354  $ja\delta_2$ .

In case 3, there is state 
$$s_{j-1}^* = (l', x, c_2, a', t') \in R_{j-1}^*$$
 satisfying inequalities  $l' < l$ 

and 
$$t' < t + l - \sum_{k=1}^j p_k - c_2 p_j + (j-1)\delta_1 + (j-1)a\delta_2$$
. By iteration phase of

357 FDPAA-SPT, 
$$s_j = (l', c_1, c_2, a' + 1, t' - l' + \sum_{k=1}^{j} p_k + (c_2 - c_1)p_j) \in R_j$$
 is produced.

358 According to elimination phase of FDPAA-SPT, there is a state 
$$s_j^* =$$

359 
$$(l'', 1, c_2, a'', t'') \in R_j^*$$
 locating in the same subinterval of  $R_j$  with  $s_j$ . And  $l'' \le l' \le l$ 

360 holds. Hence 
$$t'' \le t' - l' + \sum_{k=1}^{j} p_k + (c_2 - 1)p_j + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_j + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_1 \le t + l - \sum_{k=1}^{j} p_k + (c_2 - 1)p_k + \delta_2$$

361 
$$1)p_j + (j-1)\delta_1 + (j-1)a\delta_2 - l' + \sum_{k=1}^{j} p_k + (c_2 - 1)p_j + \delta_1 = t + (l-l') + j\delta_1 + l'$$

362 
$$(j-1)(a-1)\delta_2$$
. Since  $l' \ge l-j\delta_2$ ,  $t'' \le t+j\delta_1+j\delta_2+(j-1)(a-1)\delta_2 < t+j\delta_2$ 

 $j\delta_1 + ja\delta_2$ .

In case 4, there is state 
$$s_{j-1}^* = (l', c_1, y, a', t') \in R_{j-1}^*$$
 satisfying inequalities  $l' < l$ 

and 
$$t' < t - T_2 + l - \sum_{k=1}^j p_k - \mu + (j-1)\delta_1 + (a-1)\delta_2$$
. By iteration phase of

366 FDPAA-SPT, 
$$s_j = (l', c_1, 1, a' + 1, t' + T_2 - l' + \sum_{k=1}^{j} p_k + \mu) \in R_j$$
 is produced.

367 According to elimination phase of FDPAA-SPT, there is a state 
$$s_j^* =$$

368 
$$(l'', c_1, 1, a'', t'') \in R_j^*$$
 locating in the same subinterval of  $R_j$  with  $s_j$ . Hence  $t'' \le$ 

369 
$$t' + T_2 - l' + \sum_{k=1}^{j} p_k + \mu \le t - T_2 + l - \sum_{k=1}^{j} p_k - \mu + (j-1)\delta_1 + (j-1)a\delta_2 + k$$

- 370  $T_2 l' + \sum_{k=1}^{j} p_k + \mu \le t + j\delta_1 + ja\delta_2$ .
- 371 All the four cases meet theorem 3, thus theorem 3 holds. Hence there is a state
- 372  $s_n^* = (l', c_1, c_2, a', t') \in R_n^*$  satisfying inequalities l' < l and  $t < t + n\delta_1 + na\delta_2 = l'$
- 373  $t + \varepsilon \frac{L}{2} + \varepsilon \frac{aT_1}{2}$ . Note that job n is processed after  $T_2$ , thus  $t > aT_1$ . Hence  $t < t + \varepsilon \frac{L}{2} +$
- 374  $\varepsilon \frac{aT_1}{2} = (1 + \varepsilon)t$ . FDPAA-SPT get a  $(1 + \varepsilon)$  approximate solution.
- Theorem 4. The complexity of FDPAA-SPT is  $O(\frac{n^5}{\epsilon^2})$ .
- **Proof.** In every iteration phase of FDPAA-SPT,  $\left[\frac{V}{\delta_1}\right] \times \left[\frac{T_1}{\delta_2}\right]$  subintervals which
- occupying  $\frac{4n^2 V}{\varepsilon^2 L}$  space are produced. Since *n* is the maximum value of  $c_1$  and  $c_2$ ,
- there are  $\frac{4n^4 V}{\varepsilon^2 L}$  cases in every iteration of FDPAA-SPT. And after n cycle of iteration,
- 379  $\frac{4n^5 V}{\varepsilon^2 L}$  states are produced. Hence the complexity of FDPAA-SPT is  $O(\frac{n^5}{\varepsilon^2})$ . It is very
- 380 clear that FDPAA-SPT runs in polynomial time.

In the manufacturing industry, orders are typically scheduled through batch production and delivery mode, and the probability of machine failure under highload operation is high. On this basis, we focus on a single machine batch scheduling problem with machine maintenance intervals. To solve this problem, the mathematical programming model is established. SMBSP-MI is proved to be an NPhard problem, i.e., there is no exact algorithm that can obtain the optimal solution of large-scale problems in polynomial time. Hence, we consider designing an approximation algorithm that can obtain a high-precision solution in polynomial time. Our approach is to design an accurate algorithm based on optimal rules in the first place. Considering the dimensional explosion when solving large-scale problems, some of the poor solutions obtained by DPA-SPT are eliminated to reduce the complexity down to polynomial time. A small-scale example verifies the feasibility of DPA-SPT. As for the proposed approximation algorithm, no verification of the small and medium-scale is conducted, for the verification of the small and medium-scale problem is meaningless. Besides, although the approximation algorithm theoretically has a solution in polynomial time, it still consumes a lot of calculation time, thus no large-scale calculation examples are designed for verification. On the contrary, we proved that the approximate ratio of the algorithm is  $(1 + \varepsilon)$ .
