Abstract: Disclosed herein is a fast adder design based on a novel axiomatization of mathematics, of natural and real numbers, by the author. Addition is a Finite State Machine that, on an average, takes $\log_2 n$ iterations to calculate a n -bit addition. Further, for the proposed fast adder, the probability of a n -bit addition taking $k \leq n$ iterations to complete, is equal to the probability of k consecutive heads in n fair coin tosses. The circuitry is linear and simple, in the sense that adding bits to the inputs does not complicate the circuit topology. The growth is linear, and the instruction set is constant, and hardware based. The Figures presented in this sections are numbered 1-11, and should not be confused with the figures of the previous sections which were numbered 1-6. The figures pertaining the patent, will be referenced by the abbreviation "FIG.", followed by the number of the figure.

BACKGROUND

[0001] The subject matter of the present invention is related to a general-purpose fast adder, which is designed in the form of a sequential logic circuit. Particularly, the present invention proposes a fast adder defined in terms of a finite state machine that replaces traditional carry-over algorithms of addition, based on a novel axiomatization of mathematics, by the author. The adder constitutes a direct application of this foundation of mathematics which serves as supporting material for several aspects, including further applications, of the Simple and Linear Fast Adder.

[0002] Efficient and inexpensive Central Processing Units (CPUs) or processing units with low dissipation are an ever growing priority. One of the crucial subunits of the CPUs is an Arithmetic Logic Unit (ALU). Typically, the ALU is responsible for performing the actual arithmetic and logical operations in the CPUs. The efficiency and performance of the ALU generally depends on specific components of the ALU, namely, the adder and the bit shift component.

[0003] One of the basic problems with an existing adder, such as a Ripple Carry Adder, is the propagation delay. A traditional solution to overcome this is to use a parallel adder. Further, other solutions such as a Carry Look-Ahead (CLA), Carry Select, Carry Skip, and Carry Increment adders face their own problems. For example, in the case of CLA, if the number of bits is increased, the area and complexity of the circuit increases considerably. Therefore, the CLA fast adders of more than four bits are generally built using parallel 4-bit adders. This multi-level structure adds up to the propagation time delays.

[0004] In view of the above limitations in the existing adders, it would be advantageous to have an adder that offers linear growth and complexity irrespective of the increase in the number of bits.

[0005] The information disclosed in this background of the disclosure section is only for enhancement of understanding of the general background of the invention and should not be taken as an acknowledgement or any form of suggestion that this information forms

SUMMARY

[0006] It is an objective of the present invention to provide a general-purpose fast adder having a small count of 'AND' and 'XOR' logic gates, setting a new standard in the design and manufacture of ALU by providing efficiency that is comparable to parallel adders, while having a reduced material, production, and energy costs.

[0007] It is a further objective of the invention to design a fast adder that is implemented based on an arithmetic and real number model and which can be implemented for operation on signed and rational approximations to real numbers, with a few minor modifications.

[0008] It is a further objective of the invention to provide a universal fast adder of linear area, with logarithmic time delay.

[0009] In view of the foregoing, an embodiment of the present disclosure relates a general purpose fast adder that is in the form of a sequential logic circuit, based on a finite state machine that is not time constant. On an average, it takes $\log_2 n$ iterations to complete addition of two n -bit numbers. The proposed fast adder has the advantages of linear growth and complexity, in the sense that adding one bit of input requires adding a subunit consisting of four registers and five logical gates, and the subunits are connected in series. The instruction set does not increase when the number of bits is increased. The performance of the adder is potentially comparable to the existing fast adders, while using five logical gates (one XOR, and four AND) and four registers of memory, per bit of input. In an implementation according to the present invention, the four bit adder presented here uses sixteen AND gates, four XOR gates and sixteen one bit registers. This adder has linear area and complexity, and logarithmic delay. The power dissipation of the adder is theoretically constant, due to constant gate depth. Instruction set is also constant and independent of the number of bits of input.

[0010] In an implementation, the proposed invention is flexible and compatible with different signed representations. The proposed ALU architecture is able to support operands for integer and rational approximations to real numbers. As an example, the operations can include, without limiting to, left/right shift (multiplication/division by 2), addition, signed operations, and other operations derived thereof. Additionally, the present invention also proposes a three operand adder.

[0011] In an embodiment of the present disclosure, the four-bit adder component is configured to support a plurality of operands for integer type data and rational approximations to real number type data.

[0012] In another embodiment of the present disclosure, the four-bit adder component is configured to perform operations comprising at least one of left shift operation, right shift operation, addition, signed operations and one or more derived operations. In an embodiment, performing the operations comprises representing the numbers in a binary form in corresponding set of natural numbers, such that, each number is a set of smaller natural numbers, wherein elements of the set of smaller numbers are denoted in powers of 2 in a binary representation.

[0013] In another embodiment of the present disclosure, the linear fast adder comprises determining a symmetric difference corresponding to the operations performed at the four-bit adder component, the determining comprising saving an initial state of the op-

erations in at least one one-bit registers in the four-bit adder component, directing output of each of the one-bit registers in two disjoint paths and computing the symmetric difference and intersection in the output of each of the one-bit registers. In an embodiment, the bit configurations saved in the one-bit registers are passed through at least one XOR gate in the four-bit adder component for yielding the symmetric difference. The bit configurations saved in the one-bit registers are passed through at least one AND gate in the four-bit adder component for determining intersection in the output.

[0014] In another embodiment of the present disclosure, to represent a rational approximation of non-negative real numbers, a fraction of the bits is used for the rational part and the remaining bits are used for the integer part.

[0015] In another embodiment of the present disclosure, adding a single bit to the operands requires adding of a sub-unit of four bits and five logic gates in a linear manner to the four-bit adder component.

[0016] In another embodiment of the present disclosure, the time taken by the linear fast adder is equal to the sum of the two gate delays, and the reading and writing process.

[0017] In another embodiment of the present disclosure, clock cycles for the linear fast adder remain shorter depending on the gate depth and constant instructions, such that an increase in speed of memory writing process results in a compounded reduction of time.

[0018] In another embodiment of the present disclosure, an instruction set associated with the linear fast adder is constant and is independent of the number of bits of input provided to the linear fast adder.

[0019] In another embodiment of the present disclosure, the operation of the linear fast adder is controlled based on an arithmetic model that defines addition operations in terms of a finite state machine. Here, each state of the finite state machine comprises two columns and each column represents a finite configuration of energy levels representing one natural number. In a subsequent state of the finite state machine, the finite configuration on the left column of the two columns represents the energy levels that are not repeated in the preceding state and the finite configuration on a right column of the two columns represents objects that are repeated from the preceding state.

[0020] The foregoing summary is illustrative only and is not intended to be in any way limiting. In addition to the illustrative aspects, embodiments, and features described above, further aspects, embodiments, and features will become apparent by reference to the drawings and the following detailed description.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] The accompanying drawings, which are incorporated in and constitute a part of this disclosure, illustrate exemplary embodiments and, together with the description, explain the disclosed principles. In the figures, the leftmost digit(s) of a reference number identifies the figure in which the reference number first appears. The same numbers are used throughout the figures to reference like features and components. Some embodiments of system and/or methods in accordance with embodiments of the present subject matter are now described, by way of example only, and regarding the accompanying figures, in which:

[0022] FIGURE 1 shows a graphical representation of an exemplary operation ($15 + 23 = 38$), in accordance with some embodiments of the present disclosure.

[0023] FIGURE 2 shows an external view of one-bit data register, in accordance with some embodiments of the present disclosure.

[0024] FIGURE 3 illustrates use of exemplary registers RA/RA' and RB/RB' with input "i", output "o" and logic gates, in accordance with some embodiments of the present disclosure.

[0033] It should be appreciated by those skilled in the art that any block diagrams herein represent conceptual views of illustrative systems embodying the principles of the present subject matter. Similarly, it will be appreciated that any flow charts, flow diagrams, state transition diagrams, pseudo code, and the like represent various processes which may be substantially represented in computer readable medium and executed by a computer or processor, whether such computer or processor is explicitly shown.

DETAILED DESCRIPTION

[0034] In the present document, the word "exemplary" is used herein to mean "serving as an example, instance, or illustration." Any embodiment or implementation of the present subject matter described herein as "exemplary" is not necessarily to be construed as preferred or advantageous over other embodiments.

[0035] While the disclosure is susceptible to various modifications and alternative forms, specific embodiment thereof has been shown by way of example in the drawings

and will be described in detail below. It should be understood, however, that it is not intended to limit the disclosure to the specific forms disclosed, but on the contrary, the disclosure is to cover all modifications, equivalents, and alternatives falling within the scope of the disclosure.

[0036] The terms “comprises”, “comprising”, “includes”, or any other variations thereof, are intended to cover a non-exclusive inclusion, such that a setup, device, or method that comprises a list of components or steps does not include only those components or steps but may include other components or steps not expressly listed or inherent to such setup or device or method. In other words, one or more elements in a system or apparatus preceded by “comprises... a” does not, without more constraints, preclude the existence of other elements or additional elements in the system or method.

[0037] In the following detailed description of the embodiments of the disclosure, reference is made to the accompanying drawings that form a part hereof, and in which are shown by way of illustration specific embodiments in which the disclosure may be practiced. These embodiments are described in sufficient detail to enable those skilled in the art to practice the disclosure, and it is to be understood that other embodiments may be utilized and that changes may be made without departing from the scope of the present disclosure. The following description is, therefore, not to be taken in a limiting sense.

[0038] An overview of the proposed invention:

[0039] For a better understanding of the proposed invention, the following paragraphs provide an introduction to the simple mathematical background of the arithmetic logic and provide a general overview of the invention. In an embodiment, the numbers are written in binary form. However, instead of treating numbers as a sequence of binary symbols, they are treated as sets of natural numbers. For example, the integer seven, $7 = 111$ in binary form, would be represented as the set of natural numbers $\{0, 1, 2\}$. The number twelve, $12 = 1100$, is represented by the set $\{2, 3\}$. The number 21 = 10101 is represented by the set $\{0, 2, 4\}$. Each natural number is a set of smaller natural numbers, and the elements of the set are the powers of 2 in binary representation.

[0040] Similarly, addition is also treated in terms of sets, and not sequences. For example, consider the sum $7 + 13 = (2^0 + 2^1 + 2^2) + (2^0 + 2^2 + 2^3)$, which is the sum of sets $\{0, 1, 2\} \oplus \{0, 2, 3\}$. Here, two new sets are formed - symmetric difference and intersection. That is, the powers that are not repeated $\{1, 3\}$, and the powers that repeat $\{0, 2\}$. To add a power of 2 with itself (i.e., numbers in the intersection), simply add “1” to that power, $2^n + 2^n = 2^{n+1}$. Therefore, the sum can be rewritten as $7 + 13 = (2^1 + 2^3) + (2^{0+1} + 2^{2+1})$. The first term, $2^1 + 2^3$, represents the symmetric difference $A \triangle B$, while the second term $2^{0+1} + 2^{2+1} = (2^0 + 2^2) + (2^0 + 2^2)$ represents the intersection. The sum has been reduced to $7 + 13 = (2^1 + 2^3) + (2^1 + 2^3)$. Iterating, there is no symmetric difference. And, adding “1” to the repeated powers gives $7 + 13 = 2^{1+1} + 2^{3+1} = 2^2 + 2^4 = 20$.

[0041] If A, B are two finite sets of natural numbers, they can be added using the same method. Form two new sets $A' = A \triangle B$ and $B = s(A \cap B)$, where s is the function that adds one unit, to the elements of $A \cap B$. Then $A + B = A' + B'$. It is guaranteed that, in a finite number of iterations, the intersection $A^{(k)} \cap B^{(k)} = \emptyset$ becomes the empty set. This yields the final answer $A^{(k+1)}$, because

$$\begin{aligned} A + B &= A^{(k+1)} + B^{(k+1)} \\ &= A^{(k+1)} + s(\emptyset) \\ &= A^{(k+1)} \end{aligned}$$

[0042] A second example is $15 + 23 = 38$ of FIG. 1. The operands in the initial state are $A = \{0, 1, 2, 3\}$, and $B = \{0, 1, 2, 4\}$ because $15 = 2^0 + 2^1 + 2^2 + 2^3$ and $23 = 2^0 + 2^1 + 2^2 + 2^4$. The second state is $A' = A \triangle B = \{3, 4\}$, and $B' = s(A \cap B) = \{0 + 1, 1 + 1, 2 + 1\} = \{1, 2, \}$. The next state is given by $A'' = A' \triangle B' = \{1, 2, 4\}$ and $B'' = s(A' \cap B') = \{3 + 1\} = \{4\}$. Iterating again gives $A''' = \{1, 2\}$ and $B''' = \{4 + 1\} = \{5\}$. Iterating once more, a stable state is reached; $A^{(4)} = \{1, 2, 5\}$ and $B^{(4)} = 0$.

[0043] The process described herein is a finite state machine. Each state is composed of two columns. Each column is a finite configuration of energy-levels representing one natural number, as is illustrated in FIG. 1. A particle in the basic level "0" is worth 1 unit, and a particle in level "1" is worth 2 units. A particle in level "2" is worth 4 units, and in general a particle in level "n" is worth 2^n units. A finite configuration of particles in a column represents a set number, so that each state is a pair of natural numbers. As shown in FIG. 1, the initial state $S(t_0)$ is given by the inputs A, B . The next state, $S(t_1)$ is given by two new columns. The configuration of the left column is given by the energy levels that were not repeated in state $S(t_0)$. The right column in $S(t_1)$ is given by the repeated objects, displaced one level up. The configuration of state $S(t_2)$ is defined similarly in terms of state $S(t_1)$. The left column of state $S(t_2)$ is given by the energy levels not repeated in state $S(t_1)$. The configuration in the right column of state $S(t_2)$ is given by the energy levels repeated in state $S(t_1)$ but displaced one level up. In general, the left column of state $S(t_{k+1})$ is given by the energy levels not repeated in state $S(t_k)$. The right column of state $S(t_{k+1})$ is given by a displacement, one level up, of the energy levels repeated in state $S(t_k)$. In a finite number of steps, a stable state is reached, where no particle occupies the right column. The result of the sum is given in the left column.

[0044] In an embodiment, the basic idea behind the circuit implementation of this addition algorithm is to receive two inputs A, B and output two new numbers $A' = (A \triangle B)$ and $B' = s(A \cap B)$. These two new numbers will satisfy $A' + B' = A + B$. Iterate the process using A', B' as new inputs, to obtain A'', B'' which satisfies $A'' + B'' = A + B$. In a finite number of iterations $B^{(k)}$ becomes zero. For a finite integer k , it is true that $B^{(k)} = 0$ and the sum is $A^{(k)} = A + B$. This process will take, on average, $\log_2 n$ steps, where n is the number of bits. It takes at most n steps to terminate, and the probability for the process to end in $k \leq n$ steps is the probability of k successive heads in n coin tosses.

[0045] In an embodiment, to add two n bit numbers, four n bit registers, RA, RA' and RB, RB' are required. For example, RB' is the register of bits $RB'0, RB'1, \dots, RB'(n-1)$. Registers will have "set" and "enable" connections for read and write functions, respectively. When registers RA and RB are on "set", registers RA' and RB' are on "enable". Similarly, when registers RA and RB are on "enable", registers RA' and RB' are on "set".

[0046] In an embodiment, the initial state $S(t_0)$ is saved in the RA and RB registers. These registers output their stored memory which will go through two different paths. One path will treat symmetric difference and the other will handle the intersection. The bit configuration saved in RA, RB is enabled to go through XOR gates, yielding symmetric differences. The definition of symmetric difference is equivalent to the truth table of the XOR gate. The output of each XOR gate will be saved in the same significant bit of the RA' register. On the second path, intersection is determined by AND gates. The output of each AND gate will be saved in the next significant bit of the RB' register. The intersection is displaced one level up, and this is reflected with the bit shift. At this point, state $S(t_1)$ is stored in registers RA', RB' . This represents the first iteration of our finite state machine. The bits stored in registers RA', RB' will be enabled to move through the XOR and AND gates. The result will be saved in the RA, RB registers, storing state $S(t_2)$ in registers RA, RB . Continue to move back and forth in this manner until the stopping condition is met. The stopping condition is that the output of RB/RB' (whichever is enabled) is equal

to the zero vector.

[0047] The following components are needed. Four n bit registers, RA, RA', RB, RB' . A total of n XOR gates, and $4n$ AND gates with bit shift. The XOR determines symmetric difference and stores the results in the same significant bit. The AND gates provide the intersection, and the bit shift represents the rule $2^k + 2^k = 2^{k+1}$ applied to the objects of the intersection. Additionally, a Zero Flag "Z" checks for the stopping condition. Namely, that the right column, RB/RB' is off. The Zero Flag will take the value "Z=1" if any of the outputs from register RB/RB' are "1". It will take the value "Z=0" if and only if all of the outputs of register RB/RB' are "0". When the Zero Flag turns off, the Sum "S" is the set of signals S_0, S_1, S_2, S_3 , which are output from register RA/RA' .

[0048] A bit shift requires three iterations to complete. Multiplication by 2 is the addition $s(A) = A \oplus A = 2 \odot A$. Find $A' = A \triangle A = 0$ and $B' = s(A \cap A) = s(A)$. The result is a displacement of A , one unit up, saved in register RB' . One more iteration gives $A'' = A' \triangle B' = 0 \triangle s(A) = s(A)$ and $B'' = s(A' \cap B') = s(0 \cap s(A)) = s(0) = 0$. In the third and final iteration, the stopping condition is met, because register RB outputs the zero vector. The sum is the output "S", of register RA .

[0049] Configuration and operation of the depackaging assembly:

[0050] In an embodiment, the functioning of each individual register is explained in detail in the following paragraphs. There is one data input "i" and one data output "o". Additionally, two more input signals are included. A set signal "s" to write, and an enable signal "e" to read. If "s" is a high signal "1", the data input "i" is stored in memory. If "e" is high, then the last input saved on memory is the data output "o" of the register. The external view of the data latch is shown in FIG. 2. The process described here will never have "e" and "s" on at the same time (nor will "e'" and "s'" be on at the same time). When one is on the other is off, so that the bits will never read and write simultaneously to avoid error. Only "s,e'" are on at the same time, as are "e,s'". This same function can be described using different read and write processes. The first model presented here, for illustrative purposes, is a level triggered version. A more efficient alternative is later described in this document using dual edge triggered flip flops which require a much more simple CU.

[0051] In an embodiment, implementation of the n -bit ALU requires four n bit registers, RA, RB, RA', RB' . This is shown in FIG. 3. Registers are arranged so that XOR and AND gates are placed in between the two columns of registers RA/RA' on the left and RB/RB' on the right. The output of the XOR gates is directed into registers RA/RA' , while the output of the AND gates is directed into registers RB/RB' with a bit shift. Symmetric difference of the two columns will be saved in the left column RA/RA' , and the intersection with a bit shift will be saved in the right column RB/RB' . For every bit of input, a subunit of two gates and four bits of memory is required.

[0052] The data inputs " $i = A_0, A_1, A_2, A_3$ " and " $i = B_0, B_1, B_2, B_3$ " are only activated at the beginning of the instruction set. At the same time, a high set signal "s" is activated. The result is that the initial state $S(t_0)$ is stored in registers RA, RB . The Zero Flag "Z", and Sum "S" are also shown in FIG. 3. The connections "Z" and "S" are outputs of the registers; inputs to the CU. The Zero Flag determines if the stopping condition is met, "Z=0". Namely, that the output from register RB/RB' is zero, 0000. The "S" connections coming from register RA/RA' will represent the resulting sum, when the stopping condition is met. A Carry Flag "CF" connection is included.

[0053] The Input/Output connections and logic gates are placed on the top layer, while "Z" and "S" are on a second layer, below the latter. This is shown in FIG. 4. In an embodiment, the set and enable connections of FIG. 4, "s,e,s',e'" are each on their own layer so they do not intersect with each other, nor with the top two layers. The four layers of set and enable connections are represented by four thin lines that do not intersect. They function in the following manner. If "s'" (write RA', RB') is on, then "e" (read RA, RB) is on simultaneously. Similarly, if "e'" (read RA', RB') is on, then "s" (write RA, RB) is on.

[0054] A total of six layers of connections are needed. Four bottom layers for set and enable connections, and the two top layers for "i", "o" and "Z", "S". Three different line thicknesses are used in FIG. 4 to reflect this. Thin lines are used for the set "s" and enable "e" connections and they are placed at the bottom. Thick lines are placed on top of the four layers of thin lines and are used for "Z" and "S". Medium thickness lines are placed at the top layer and are used for input "i" and output "o".

[0055] The first step in the process is to write the data input signals $i = A_0, B_0, A_1, B_1, A_2, B_2, A_3, B_3$ in the registers $RA_0, RB_0, RA_1, RB_1, RA_2, RB_2, RA_3, RB_3$, respectively. The data connections appear at the bottom of the Control Unit in FIG. 4. This first step is achieved by activating the data input "i" signals, along with the set "s" signal. The input signals are on low "0" or high "1" according to the inputs A, B being represented. The input connections are activated only once at the beginning of the instruction set. Simultaneously, the set signal "s" is high "1". There is one exception. After the initial data input into RB_0 , the bit shift requires a "0" input into RB'_0 , then it will require low "0" to be input into RB_0 . This continues in an alternate manner until the stopping condition is met. This is specified in the instruction set. A "0" signal is sent to RB'_0 , the first time "s'" is activated, and every iteration after that "0" is sent to RB_0/RB'_0 in an alternate manner as explained.

[0056] In an embodiment, the second step is to output the data signal "o" of the RA, RB registers. This is achieved with a high enable "e" signal. The data outputs of RA, RB will go through the XOR and AND gates. At the same time "s'" is also on, so that RA', RB' registers write the output of the gates. The result is that the second state of the finite state machine is saved in the RA', RB' registers. The next iteration is to output the bits stored in RA', RB' and write the result on the RA, RB bits. This is achieved by turning on "e'" and "s" simultaneously. The third state of the system is stored in memory, in the RA, RB registers. Continuing in this manner for a finite number of iterations leads to a stable state; the output of register RB/RB' will be 0000 in a finite number of states. The result is the Sum "S" output of register RA' .

[0057] FIG. 5 shows a flow diagram for the instruction set, where the instruction set is constant and independent of the bit length of inputs, in accordance with some embodiments of the present disclosure. The instruction set for the flow diagram is given below:

1. Load data inputs $i = A_i, B_i$ to registers RA_i, RB_i , and activate Set "s=1".
2. Activate Enable "e=1" and Set "s'=1". Load data input "i=0" to RB'_0 bit.
3. Read Zero Flag "Z"
 - If "Z=0", Get "S";
 - Else "Z=1", Activate Enable "e'=1" and Set "s=1". Load data input "i=0" to RB_0 bit.
4. Read Zero Flag "Z"
 - If "Z=0", Get "S";
 - Else "Z=1", Go to II.

These instructions can be carried out largely by Hardware. This will be explained later in the document.

[0058] An example is illustrated in the following paragraphs. Let $A = 6 = 0110$ and $B = 3 = 0011$. The corresponding instructions are listed below:

- I. First instruction will load inputs $A = 0110$ and $B = 0011$ to registers RA, RB . That is, $RA0 = 0, RA1 = 1, RA2 = 1, RA3 = 0$, and $RB0 = 1, RB1 = 1, RB2 = 0, RB3 = 0$.
- II. Subsequent instruction will read the contents of registers RA, RB . These contents are directed to the XOR and AND gates. The output of these is written on the RA', RB' registers. In our example, the outputs of $RA0, RB0$ are "0,1", respectively. These outputs will then be directed to the XOR0 gate, and input "1" into $RA'0$. Simultaneously, the same "0,1" outputs, from $RA0, RB0$, will also be directed into the AND0 gate which will input "0" into $RB'1$. In an embodiment, the output of registers $RA1 = 1, RB1 = 1$ will input "0" into $RA'1$ and "1" into $RB'2$, after going through gates XOR1 and AND1, respectively. The outputs of $RA2 = 1, RB2 = 0$ will write "1" into $RA'2$ and "0" into $RB'3$ after passing through XOR2 and AND2. Also, $RA3 = RB3 = 0$ will write "0" into $RA'3$. The bit-shift requires the CU to input "0" into $RB'0$. While these outputs go through the gates and the results are written, the output of the RA, RB registers will be sent to the CU in the form of " $S_0 = 0, S_1 = 1, S_2 = 1, S_3 = 0$ " and " $Z=1$ ", respectively.
- III. The subsequent instruction will read " $Z=1$ ". The action path is to read RA', RB' and write the results on registers RA, RB . The results are $RA0 = 1, RB0 = 0, RA1 = 0, RB1 = 0, RA2 = 0, RB2 = 0, RA3 = 0, RB3 = 1$. Again, the bit-shift requires a "0" input into $RB0$. At the same time, the output of RA and RB has been sent to the CU in the form of " $S_0 = 1, S_1 = 0, S_2 = 1, S_3 = 0$ " and " $Z=1$ ", respectively.
- IV. The subsequent instruction will read " $Z=1$ ". Then, go to Instruction II.
- II'. Outputs the memory of RA, RB into RA', RB' . The result will be $RA'0 = 1, RA'1 = 0, RA'2 = 0, RA'3 = 1$, and $RB'0 = RB'1 = RB'2 = RB'3 = 0$. At the same time, the output of RA and RB has been sent to the CU in the form of " $S_0 = 1, S_1 = 0, S_2 = 0, S_3 = 0$ " and " $Z=1$ ", respectively.
- III'. will read " $Z=1$ ". The action path is to read RA', RB' and write the results in RA, RB . At the same time, the output of RA', RB' is sent to the CU as " $S_0 = 1, S_1 = 0, S_2 = 0, S_3 = 1$ " and " $Z=0$ ", respectively. This concludes the program, with "S" being the result of addition of the original inputs; $6 + 3 = 9$.

[0059] To represent a rational approximation of a non-negative real number, a fraction of the bits is used for the rational part and the remaining bits are used for the integer part. This gives us operation for fixed point rational numbers. The examples given are of fixed point nature. However, this ALU architecture is compatible with floating point representation and operations.

[0060] Negative energy levels are identified with negative powers of 2. Therefore, a set of negative integers will give a unique number in the unit interval $[0, 1]$. For example, the set $\{-1\}$ is the number $\frac{1}{2} = 2^{-1}$. The set representation of $\frac{3}{4} = 2^{-1} + 2^{-2}$ is the set $\{-1, -2\}$. Consider the finite state machine of FIG. 1. Notice that changing the labels on the energy levels gives a new expression. For example, making the bottom level equal to 3, instead of 0. This means 3 is added to every element of a set number. Instead of $15 + 23 = \{0, 1, 2, 3\} \oplus \{0, 1, 2, 4\}$, the new addition is $\{0 + 3, 1 + 3, 2 + 3, 3 + 3\} \oplus \{0 + 3, 1 + 3, 2 + 3, 4 + 3\} = \{3, 4, 5, 6\} \oplus \{3, 4, 5, 7\} = 120 + 184$. The new result is obtained by adding 3 to all the elements of the original result, $\{1 + 3, 2 + 3, 5 + 3\} = \{4, 5, 8\} = 304$.

[0061] In an embodiment, if the energy levels are displaced into negative integers, the results still hold a true expression. In FIG. 6, an example of this is provided. The addition of sets with negative integers in its elements is the same as before. The addition $\frac{1}{4} + \frac{1}{4} = \{-2\} \oplus \{-2\}$ is equal to $\frac{1}{2} = \{-1\}$. The set addition is $(\{-2\} \triangle \{-2\}) \oplus s(\{-2\} \cap \{-2\})$; first term is the empty set, and the second term is $s(\{-2\}) = \{-2 + 1\} = \{-1\}$.

[0062] The circuit for adding numbers whose elements include negative integers does not require any additional components. The circuit of FIG. 4 suffices. However, to divide

numbers by 2, a second bit shift is needed. This is easily achieved by adding two enabling AND gates to each AND gate of the ALU. One gate will Enable Multiply "EM" and the other will Enable Divide "ED". Only one of these can be on at a time and must remain on during the entire time of the operation. Carry flags for multiplication "MCF" and division "DCF" are also included. This is illustrated in FIG. 7. A connection for input in $RB'3$ is also included for division, just as an input connection is included for $RB'0$.

[0063] One more component should be included in the description of the ALU. Once an addition is performed and new data inputs are to be loaded, the registers will be receiving signals from the CU and the XOR gates because when "s" is on, so is "e'". To solve this, an AND gate is placed after each XOR gate. This enables the symmetric difference just as the "ED" and "EM" gates enable the intersection. These gates will be called "EXOR", and one of its inputs is connected to the output of its corresponding XOR gate and the other is a high signal whenever "EM" or "ED" are a high signal. This is a viable solution because it also gives a two gate depth to the XOR path, as in the case of the AND path. The XOR and AND paths have equal gate depth.

[0064] In an embodiment, the control logic is designed simple enough to show in a diagram. FIG. 8 is an internal view of the Control Unit. Step I requires set connection "s" to be on. This is achieved with a high signal in "e' / s". Simultaneously, the data inputs are also sent to the registers. Step II Requires for "s' / e=1" to be turned on. This will read registers RA and RB and write on registers RA' and RB' . The output of register RB will, at the same time, be directed to the Zero Flag "Z". A "Switch Unit" is included to perform the following function. The first time "Switch Unit" receives high input " $Z=1$ ", it will output a low signal to "s' / e". The next time the switch unit receives a high signal " $Z=1$ ", it will output a high signal. That high signal will go to gate "sw" so that now a low signal is directed to "e' / s". This continues in alternating manner so that the output of the switch unit moves between high and low, starting with a low signal. When the switch unit receives a low signal, there is no output because the stopping condition has been met.

[0065] In an embodiment, the control unit has an input "D/M". If addition is to be performed, " $D/M=1$ " should be on. Bit shift equivalent to multiplication by 2 is performed if both inputs are equal. If the signal is low " $D/M=0$ ", then " $ED=1$ " and the operation performed is division by 2 when both inputs are equal. The carry out connections "DCF" and "MCF" are shown again. The "EXOR" signal is given by gates "B1" and "B2"; it is on whenever "ED" or "EM" are on. A flag "F" is included for internal use of the CU. The flag is on when the stopping condition is met; the flag turns on when "Z" turns off. It can be used to save the Sum "S" in memory once the addition is completed. It is also used to indicate when new data inputs are loaded to the registers, and it shuts off "ED", "EM" and "EXOR". The flag is also used for outputting a zero value to $RB0/RB'0$. In the case of division, the bits $RB3/RB'3$ take their place.

[0066] In an embodiment, increasing the number of input bits increases the area linearly. This is a box-car architecture, where adding a bit to the operands requires to add a sub unit of four bits and five logic gates in linear manner (add a box car). A n -bit adder requires $4n$ many bits of registers, n many XOR gates, and $4n$ many AND gates. Compared to other fast architectures, this represents a significant reduction in material resources and area. The requirements are the same number of registers, and reduced gate count, area, and complexity. Furthermore, the instruction set remains the same, for any number of bits.

[0067] The finite state machine is not time constant. Calculation time is constant for equal inputs, but differs for different inputs. Let t , the time length for one iteration, then $t \cdot \log_2 n$ is the average time to complete an addition, and the longest time is $t \cdot n$. The circuit has a fixed gate depth of two logic gates, plus the lengthiest micro steps of reading and

writing memory. This allows easy calculation of the time it takes to perform one iteration. It is equal to the sum of the two gate delays, plus the reading and writing process.

[0068] In an embodiment, the circuit is designed to have easy synchronization, independent of the choice of logic, clock speeds and register type. Particular solutions abound and are routine. The general principal of modeling the finite state machine through a logical circuit is being described. In terms of area, the CLA has area of order $O(n \log_2 n)$, while the area of the fast adder here proposed is of linear order $O(n)$. The ratio of these two orders is $O(\log_2 n)$. Approximately $\log_2 n$ many fast adders, of the type here proposed, may fit in the same space of one CLA of equal bits, as n gets bigger. Also, CLA performs in one clock cycle, while the proposed adder considers a positive number of iterations, on average $\log_2 n$ many iterations. It is concluded that performance is expected to be comparable in terms of area and speed, as the number of bits, n , and the number of operations performed, grow. This is true if the clock cycles of the compared adders are of equal time length. It must be considered that the clock cycles for the proposed adder will be shorter because the gate depth is a small constant and instructions are constant. This effect will potentially give better performance than other fast parallel adders. This design is likely to operate at higher than conventional clock speeds. If the memory writing process can be sped up, then the whole process will have a compounded reduction of time, and possibly outperform other fast adders, bit for bit.

[0069] Another advantage of the present invention would be power consumption, because the control logic and gate depths are a small constant number. The design can be adapted to specific applications such as general purpose, graphics, scientific, etc.

[0070] A second example is provided, illustrating the internal process of the adder and the control unit. This example will illustrate a bit shift to the right, which is equivalent to division by 2. In this case, let $A = B = 0111$. The result of the operation is $A + B = 0011$, and the carry flag "DCF" will be activated in the process. Load the data inputs; the set connection "s" is set to high. Simultaneously, the data inputs of A and B are activated. On every iteration that follows, the "D/M" input in the CU will be set to low so that the division gates "ED0-ED3" are enabled in the ALU. Thus, bits are carried to the right, not the left. Next, the "s'/e" input of the CU is turned on. This will enable reading of the RA, RB registers, and writing on RA', RB' registers. Specifically, registers $RA0 = 1, RB0 = 1$ will both input a high signal to gate "AND0", turning it on. Therefore, gate "ED0" will be turned on and it will be sending a signal to the division carry flag "DCF". This will simply indicate that a carry over to the right is taking place in the first bit. At the same time, the corresponding process takes place for the other bits. registers $RA1 = 1$ and $RB1 = 1$ turn gate "AND1" on. This turns gate "ED1" on, sending a high signal to register $RB'0$. A similar situation happens with the next bit, $RA2 = RB2 = 1$. These send a high signal to $RB'1$. The last bit, $RA3 = RB3 = 0$ will send a low signal to $RB'2$. Also, a low signal is sent to $RB'3$ as part of the instruction set. At the end of this process the configuration of the registers is $RA' = 0000$ and $RB' = 0011$. While this is taking place, the outputs of register RA are also sent to the Zero Flag. Since at least one of these bits is on, "Z" is on.

[0071] The high signal of "Z" will go into the switch unit which will output a low signal, initiating the second iteration. Registers $RA' = 0000$, and $RB' = 0011$ are read and then pushed through the XOR and AND gates. The output of the gates is written on registers $RA = 0011$, and $RB = 0000$, respectively. The output of the Zero Flag is "1", so a high signal goes into the switch unit which will output a high signal. This will read registers RA and RB . The output of register RB is the zero vector, so that the output of the zero flag is a low signal "Z=0". This signals RA to be saved in memory or operate where it is needed. At the same time, it will signal for the "ED", "EM", and "EXOR" to be off in the next clock cycle so that new data can be input to the registers without error. This example suggests that

it could be convenient to have a Zero Flag for register RA , also. This last implementation would subtract one iteration from the bit shift.

[0072] Two sets of registers RA, RB, RA', RB' were used because of the racing problem. The outputs of the XOR and AND gates are looped back to the registers. That is why a rudimentary master-slave solution has been illustrated. However, that solution is not the most efficient. An alternative solution is presented. A variation of the proposed ALU can be implemented using edge triggered registers. If the registers are replaced for memory bits capable of handling inputs/outputs independently and without error of feedback, then the number of memory registers is reduced. A total of two n bit registers will suffice. Edge triggered registers offer a solution. A register with three connections is used: clock "CLK", input "D", and output "Q". Each register will have to read on the positive edge and write on the negative edge of the clock cycle. This is shown in FIG. 9. Enable divide, enable multiply, and enable EXOR gates are not shown.

[0073] A three operand version is possible and comparable to Carry Save Adder. The proposed unit should yield better performance when adding positive numbers. The expected sign difficulties of CSA are still present for signed operations of three operands. A comparison is given between the gate topology for a two operand unit in FIG. 10, and a three operand unit in FIG.11.

[0074] In an embodiment, FIG. 10 shows the basic sub unit that allows for the iterative process on one-bit. It consists of a half adder where the output of AND is connected to the register $RB(i + 1)$ of the next bit, representing the new configuration in the right column of the finite state machine. The output of XOR is directed back to the RA_i register of the same bit, representing the left column.

[0075] FIG. 11 is an adaptation of the adder, for three inputs. First, there are XOR and AND gates "2" and "3". When all three inputs A, B, C are a high signal, then gates "2" and "3" both output a high signal so that the output of gate "4" is a high signal. This amounts to a high signal being sent to the RB register of the next bit. That is, a carry over. Simultaneously, a high signal is sent back to the RA register of the same bit. A unit remains in the same bit. The case when all the inputs of a bit are "1" result in a carry over and unit in the same bit. This is the only case in which gate "4" is on, so no more attention is paid to it.

[0076] In an embodiment, if only two of the three inputs are a high signal, then gates "2" and "3" will both be off. Specifically, the fact that gate "3" is off, implies that gate "5" is on. Simultaneously, two of the three gates "6, 7, 8" are on. This means gate "9" is receiving two high signals, so that its output is a high signal "1". There is a carry over and no unit remains in that bit. The next case is when only one of three inputs is on. Gate "2" is off, and gate "3" is on; a unit remains in that bit, and no carry over is generated.

[0077] In an embodiment, if all inputs are off then gate "5" will be on, but gates "6, 7, 8" will be off so that gate "9" is also off. No carry overtakes place and there is no unit remaining, all cases have now been covered. The circuit whose elements are gates "2-9" is a one bit adder for three operands. Several bits are connected in series, to iterate until the system stabilizes. The control logic will remain the same.

[0078] The terms "an embodiment", "embodiment", "embodiments", "the embodiment", "the embodiments", "one or more embodiments", "some embodiments", and "one embodiment" mean "one or more (but not all) embodiments of the invention(s)" unless expressly specified otherwise.

[0079] The terms “including”, “comprising”, “having” and variations thereof mean “including but not limited to”, unless expressly specified otherwise.

[0080] The enumerated listing of items does not imply that any or all the items are mutually exclusive, unless expressly specified otherwise. The terms “a”, “an” and “the” mean “one or more”, unless expressly specified otherwise.

[0081] While various aspects and embodiments have been disclosed herein, other aspects and embodiments will be apparent to those skilled in the art. The various aspects and embodiments disclosed herein are for purposes of illustration and are not intended to be limiting, with the true spirit being indicated by the following claims.

WHAT IS CLAIMED IS:

1. A linear fast adder for an Arithmetic Logic Unit (ALU), the adder comprising:
 - a) a four-bit adder component comprising a plurality of logic gates comprising at least sixteen AND gates, four XOR gates; and
 - b) a plurality of one-bit registers; wherein the four-bit adder is configured with a linear area, linear complexity and a logarithmic delay; and wherein the four-bit adder has a constant gate depth thereby resulting in constant power dissipation.
2. The linear fast adder of claim 1, wherein the four-bit adder component is configured to support a plurality of operands for integer type data and rational approximations to real number type data.
3. The linear fast adder of claim 1, wherein the four-bit adder component is configured to perform operations comprising at least one of left shift operation, right shift operation, addition, signed operations and one or more derived operations.
4. The linear fast adder of claim 3, wherein performing the operations comprises: representing the numbers in a binary form in corresponding set of natural numbers, such that each number is a set of smaller natural numbers, wherein elements of the set of smaller numbers are denoted in powers of 2 in a binary representation.
5. The linear fast adder of claim 1 further comprises determining a symmetric difference corresponding to the operations performed at the four-bit adder component, the determining comprising:
 - a) saving an initial state of the operations in at least one one-bit registers in the four-bit adder component;
 - b) directing output of each of the one-bit registers in two disjoint paths; and
 - c) computing the symmetric difference and intersection in the output of each of the one-bit registers.
6. The linear fast adder of claim 5, wherein the bit configurations saved in the one-bit registers is passed through at least one XOR gate in the four-bit adder component for yielding the symmetric difference.
7. The linear fast adder of claim 5, wherein the bit configurations saved in the one-bit registers is passed through at least one AND gate in the four-bit adder component for determining an intersection in the output.
8. The linear fast adder of claim 1, wherein to represent a rational approximation of non-negative real number, a fraction of the bits is used for the rational part and the remaining bits are used for the integer part.

9. The linear fast adder of claim 1, wherein adding a single bit to the operands requires adding of a sub-unit of four bits and five logic gates in a linear manner to the four-bit adder component.
10. The linear fast adder of claim 1, wherein the time taken by the linear fast adder is equal to sum of the two gate delays, and the reading and writing process.
11. The linear fast adder of claim 1, wherein clock cycles for the linear fast adder remains shorter depending on the gate depth and constant instructions, such that an increase in speed of memory writing process results in a compounded reduction of time.
12. The linear fast adder of claim 1, wherein an instruction set associated with the linear fast adder is constant and is independent of the number of bits of input provided to the linear fast adder.
13. The linear fast adder of claim 1, wherein the operation of the linear fast adder is controlled based on an arithmetic model that defines addition operations in terms of a finite state machine.
14. The linear fast adder of claim 13, wherein each state of the finite state machine comprises two columns and each column represents a finite configuration of energy levels representing one natural number.
15. The linear fast adder of claim 14, wherein in a subsequent set of the finite state machine, the finite configuration on a left column of the two columns represents the energy levels that are not repeated in the preceding state and the finite configuration on a right column of the two columns represents objects that are repeated from the preceding state.

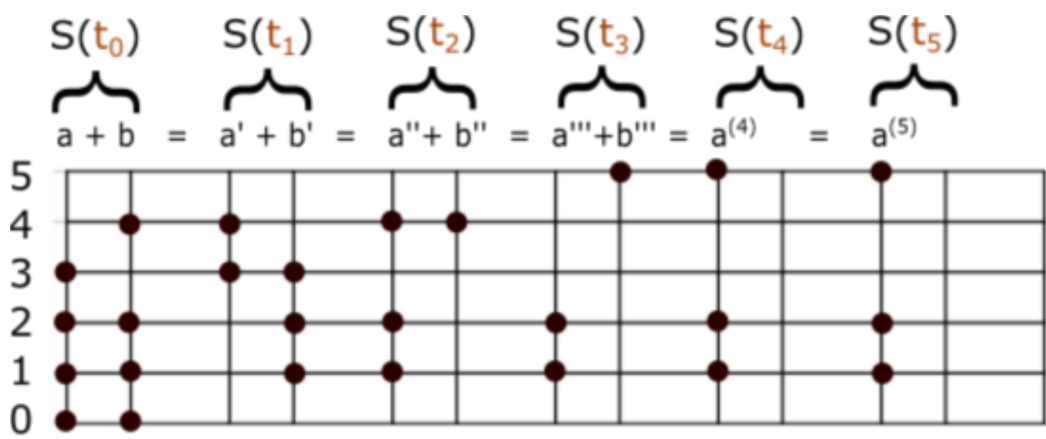

FIG. 1

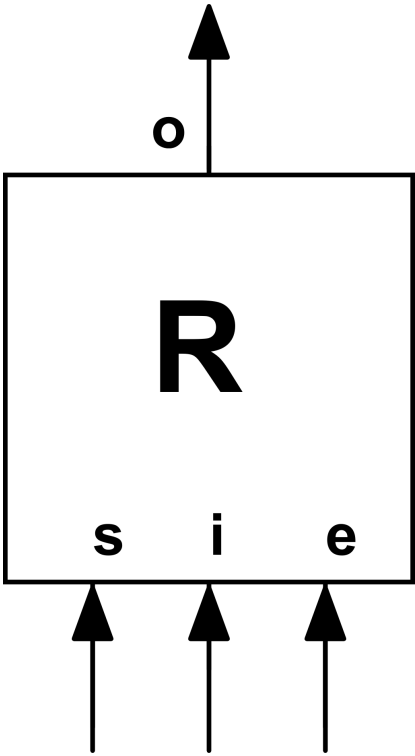

FIG. 2

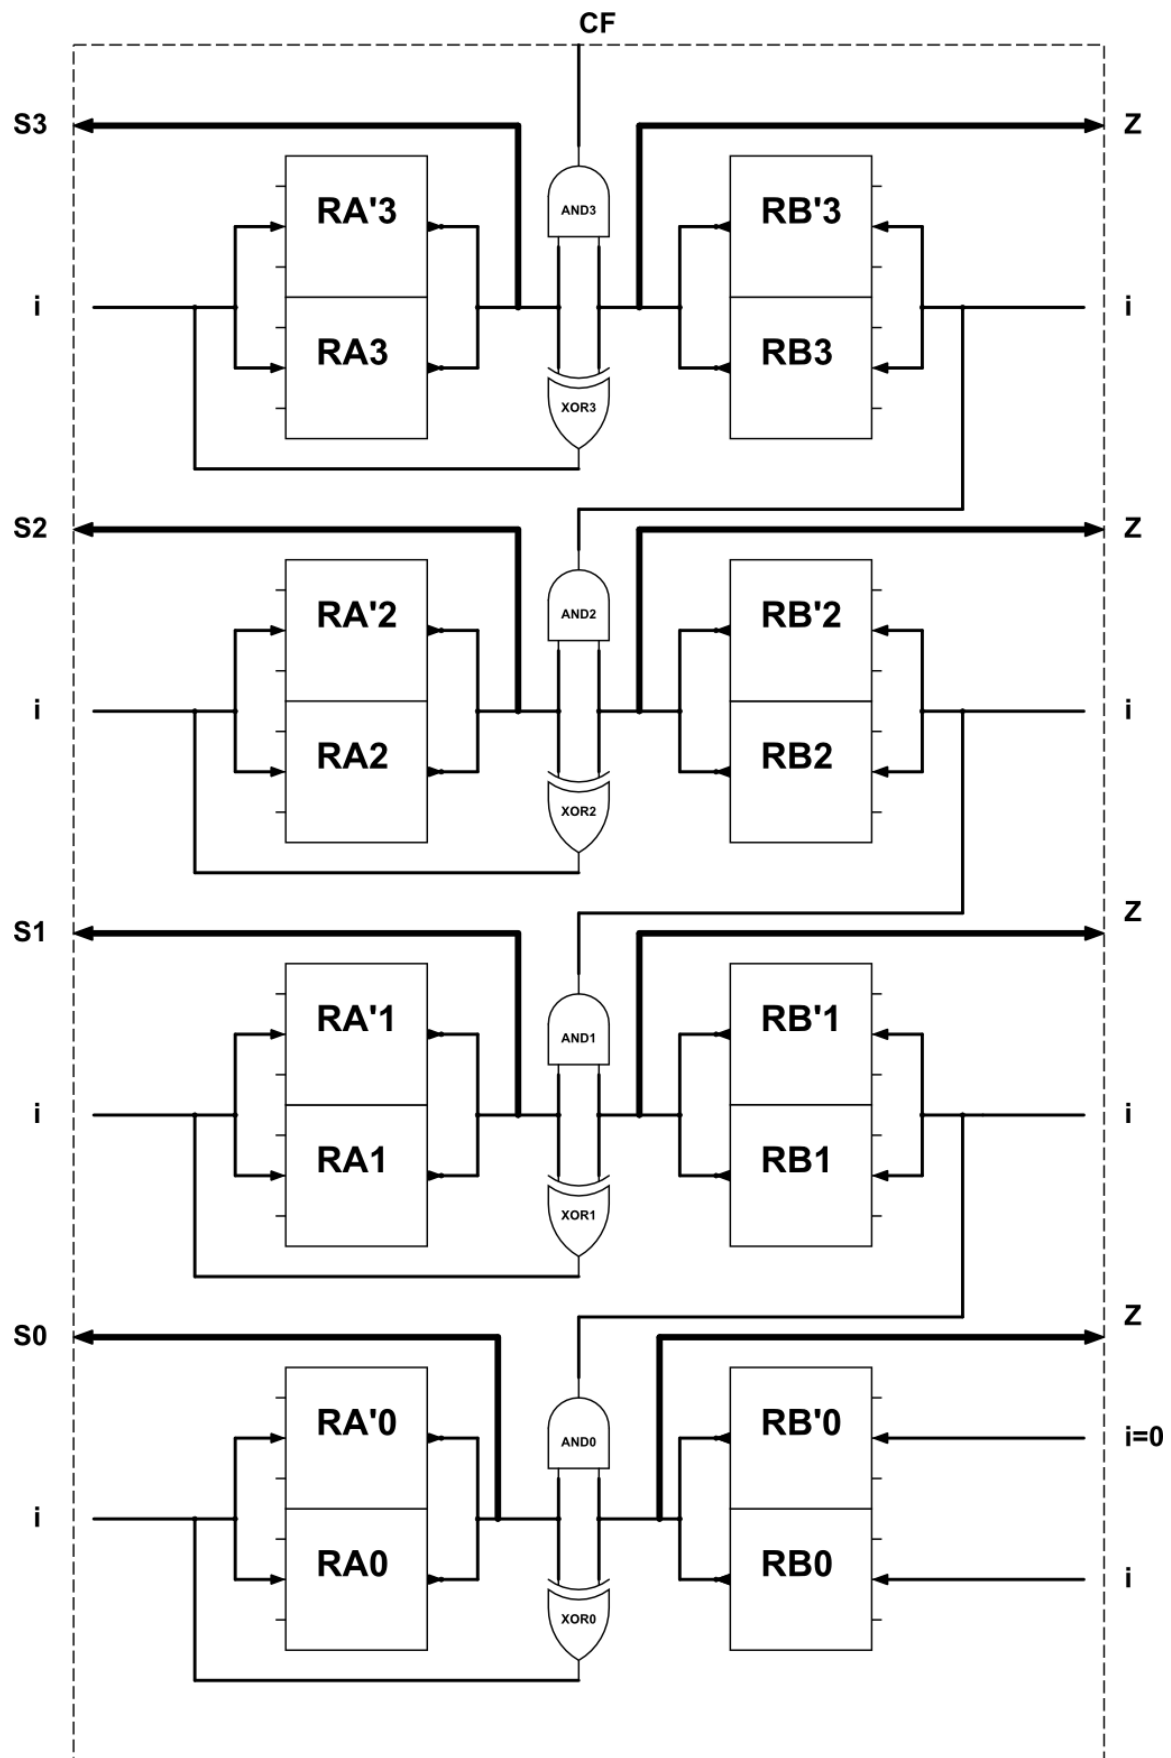

FIG. 3

FIG. 4

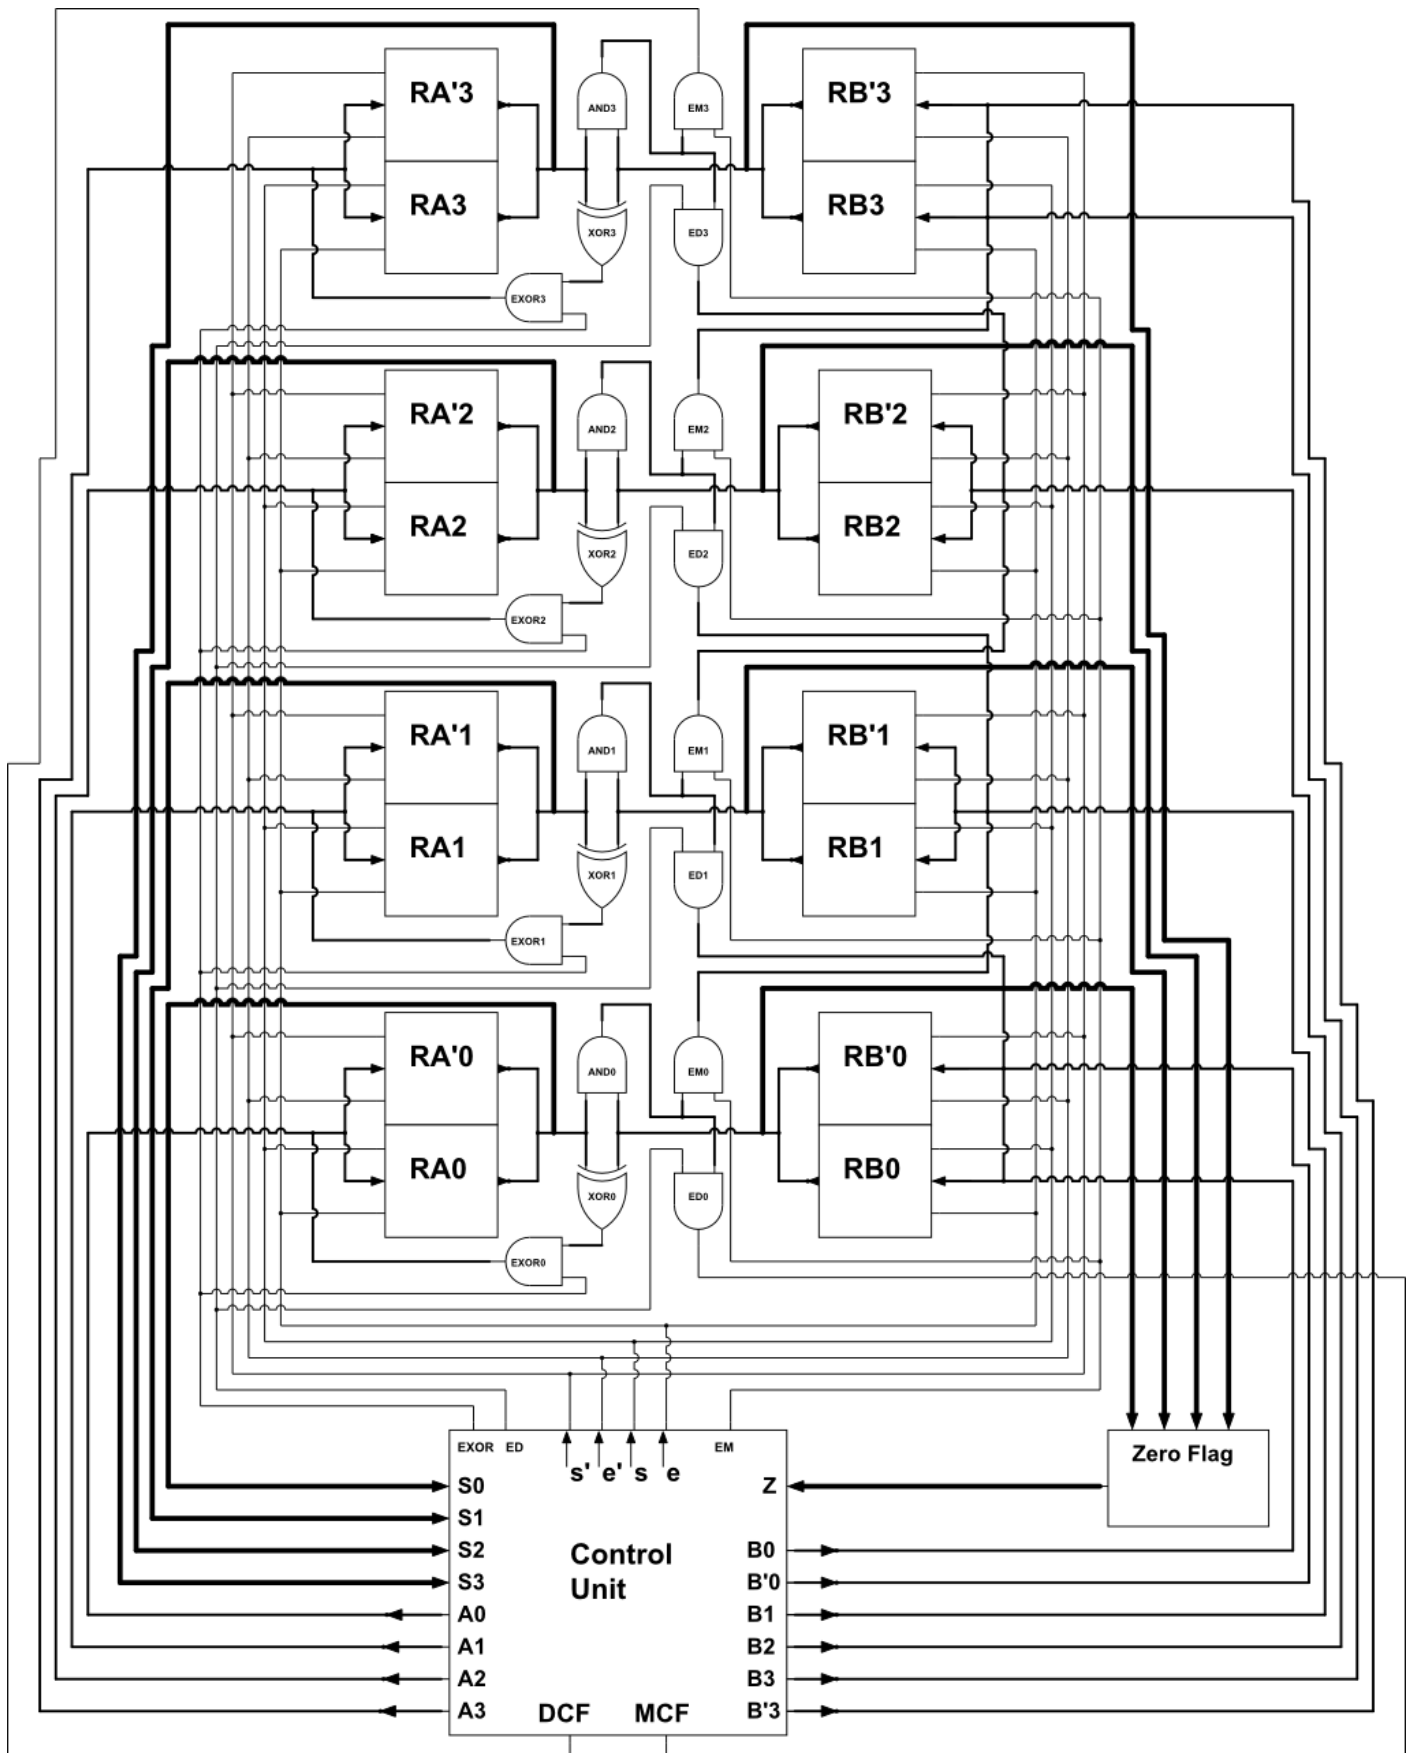

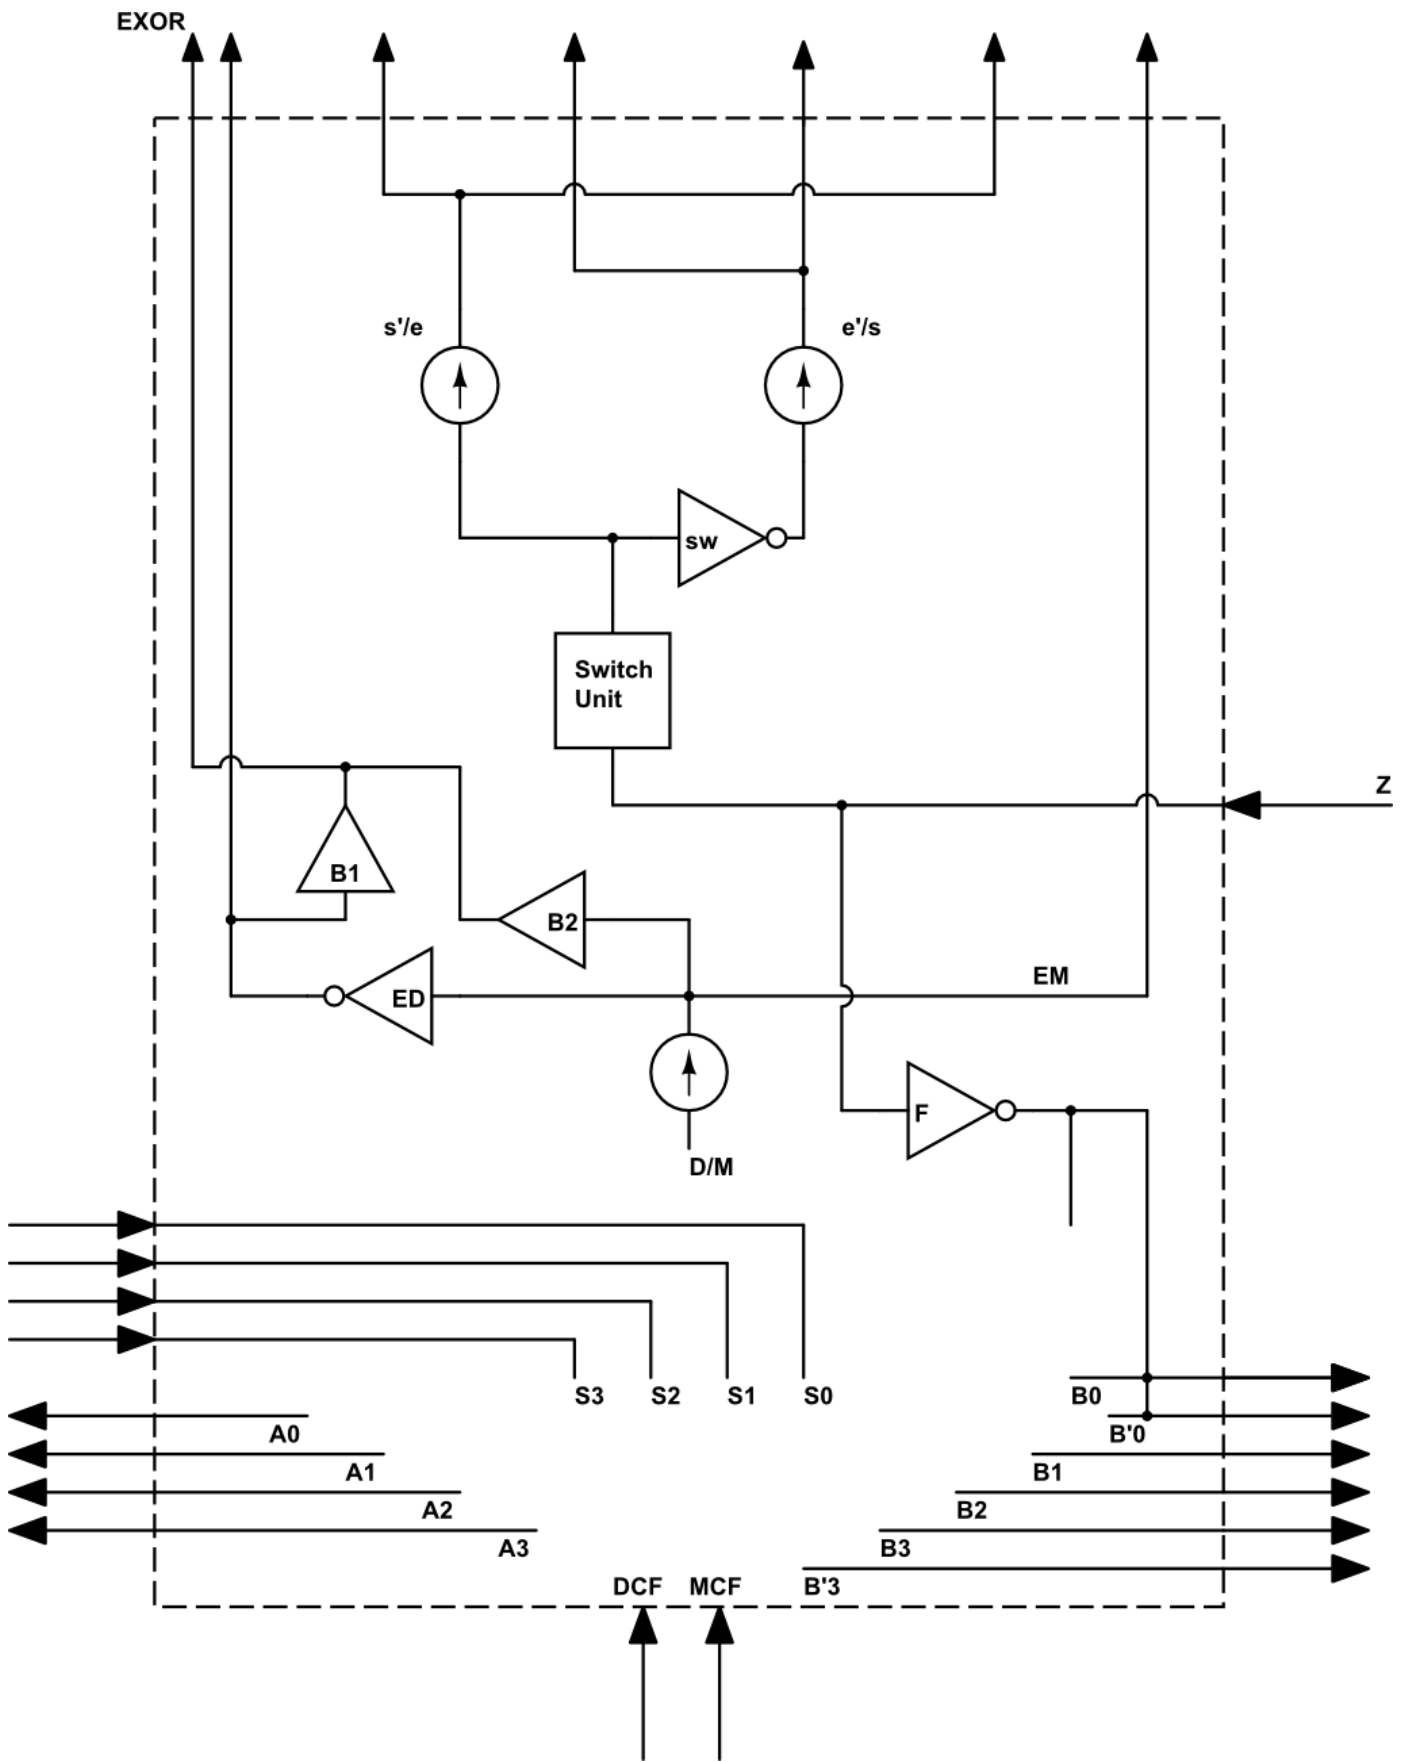

FIG. 7

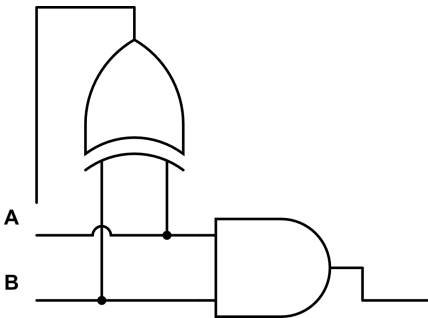

FIG. 10

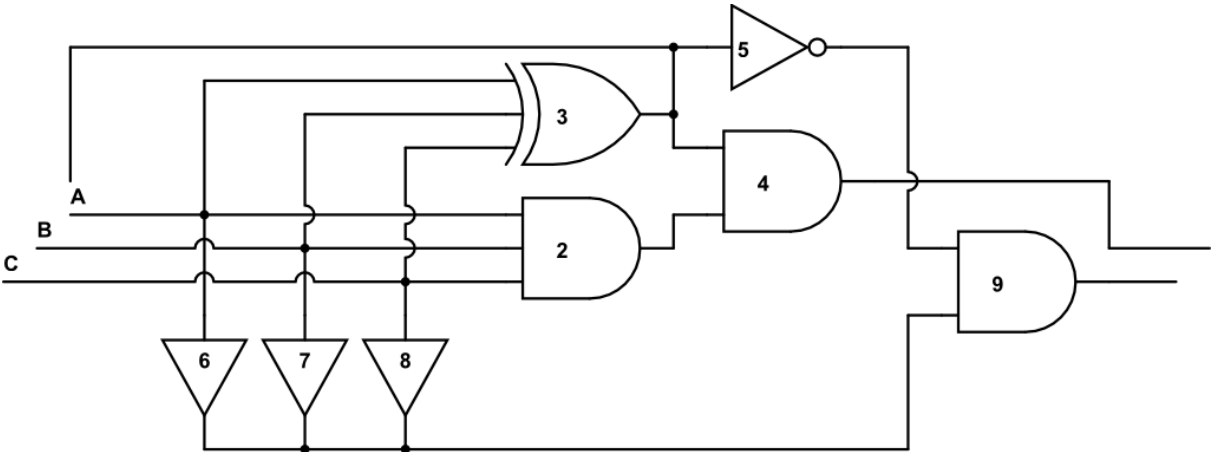

FIG. 11

Appendix .1 $|G| = 5$

If G is a group with five objects, then all non trivial objects satisfy $|g| \mid 5$. This implies $|g| = 5$, for all non trivial $g \in G$. Without loss of generality, choose any object g_1 . Then, g_1^2 is a non trivial object, g_2 . Also, $g_1 * g_2 = g_1^3$ is a new non trivial object, g_3 , etc.

e	g_1	g_2	g_3	g_4
g_1	g_2			
g_2	g_3			
g_3	g_4			
g_4	e			

Now, use the associative property to find the operation function of g_2 , and it will be placed in the second column. It is true $g_2 = g_1 * g_1$, so that it must also be true that $*g_2 = *g_1 \circ *g_1$. This means $*g_2(g_1)$ is found by $g_1 \rightarrow_{*g_1} g_2 \rightarrow_{*g_1} g_3$. Also, $*g_2(*g_2)$ because $g_2 \rightarrow_{*g_1} g_3 \rightarrow_{*g_1} g_4$, etc.

e	g_1	g_2	g_3	g_4
g_1	g_2	g_3		
g_2	g_3	g_4		
g_3	g_4	g_5		
g_4	e	g_1		

Do the same with the column of $g_3 = g_1 * g_2$ and $g_4 = g_1 * g_3$, so that $*g_3 = *g_1 \circ *g_2$ and $*g_4 = *g_1 \circ *g_3$. For example, $g_3 * g_1 = *g_3(g_1)$ is given by the arrows $g_1 \rightarrow_{*g_2} g_3 \rightarrow_{*g_1} g_4$, etc.

e	g_1	g_2	g_3	g_4
g_1	g_2	g_3	g_4	e
g_2	g_3	g_4	e	g_1
g_3	g_4	e	g_1	g_2
g_4	e	g_1	g_2	g_3

The group is defined by the number of objects, so that there exists only one group, \mathbb{Z}_5 , of five objects. To find the canonical naming functions, make $e = 4$ and $a = 3$ for some object $a \in \mathbb{Z}_5$ such that $|a| = 5$. However, all non trivial objects have order 5, so that a can be any non trivial object. To maximize the representation, the object $b = a^2$ has to be assigned the numerical value 2.

4	3	2	1	0
3	2			
2				
1				
0				

The new object $c = a * b = a^3$ is assigned value 1, and $d = a^4$ is assigned value 0.

4	3	2	1	0
3	2			
2	1			
1	0			
0	4			

The rest of the table can be found, using the associative property.

4	3	2	1	0
3	2	1	0	4
2	1	0	4	3
1	0	4	3	2
0	4	3	2	1

This numerical table is given by four different naming functions. Consider the naming function that has $e = 4$ and $g_4 = 3$. Then $g_4^2 = g_3 = 2$, and $g_4^3 = g_2 = 1$, and $g_4^4 = g_1 = 0$. This naming functions is represented by the sequence (e, g_4, g_3, g_2, g_1) . The four canonical naming functions are

$$\begin{aligned} &(e, g_1, g_2, g_3, g_4) \\ &(e, g_2, g_4, g_1, g_3) \\ &(e, g_3, g_1, g_4, g_2) \\ &(e, g_4, g_3, g_2, g_1). \end{aligned}$$

These four canonical naming functions are actually the automorphisms of \mathbb{Z}_5 , in disguise. Fix any one of these naming functions, say $A = (e, g_3, g_1, g_4, g_2)$. Let B any other canonical naming function, say $B = (e, g_2, g_4, g_1, g_3)$. The bijective function defined below is an automorphism.

$$\begin{aligned} e &\mapsto e \\ g_1 &\mapsto g_4 \\ g_2 &\mapsto g_3 \\ g_3 &\mapsto g_2 \\ g_4 &\mapsto g_1 \end{aligned}$$

Let B any other canonical naming functions, say $B = (e, g_4, g_3, g_2, g_1)$. A second automorphism has been determined,

$$\begin{aligned} e &\mapsto e \\ g_1 &\mapsto g_3 \\ g_2 &\mapsto g_1 \\ g_3 &\mapsto g_4 \\ g_4 &\mapsto g_2. \end{aligned}$$

Four automorphisms of \mathbb{Z}_5 are determined using the four canonical naming functions. The canonical representation is

$$\begin{aligned} N_{\mathbb{Z}_5} = & 2^{2^9+2} 2^{2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1)} + 2^{2^7+2} 2^{2(2^9+2^8)+2(2^7+2^6)+2(2^5+2^4)+2(2^3+2^2)+2(2^1+2^{10})+1)} \\ & + 2^{2^5+2} 2^{2(2^9+2^6)+2(2^7+2^4)+2(2^5+2^2)+2(2^3+2^{10})+2(2^1+2^8)+1)} + 2^{2^3+2} 2^{2(2^9+2^4)+2(2^7+2^2)+2(2^5+2^{10})+2(2^3+2^8)+2(2^1+2^6)+1)} \\ & + 2^{2^1+2} 2^{2(2^9+2^2)+2(2^7+2^{10})+2(2^5+2^8)+2(2^3+2^6)+2(2^1+2^4)+1)}. \end{aligned}$$

Appendix .2 $|G| = 6$

Direct Product $\mathbb{Z}_2 \oplus \mathbb{Z}_3$. Begin as usual, with the list of objects.

e	g_1	g_2	g_3	g_4	g_5
g_1					
g_2					
g_3					
g_4					
g_5					

There exists at least one element of order equal to the smallest prime divisor of 6; there is at least one object of order 2. Since 3 is a prime divisor of 6, the group has at least one object of order 3, as well. In fact, there has to be a multiple of $\phi(3) = 2$ many objects of order 3. Therefore, any group of six objects will have either two, or four, objects of order 3. First, consider the case with two objects of order 3, and three objects of order 2. Suppose, without loss of generality, $g_1^2 = g_2$ and $g_1 * g_2 = e$.

e	g_1	g_2	g_3	g_4	g_5
g_1	g_2	e			
g_2	e	g_1			
g_3			e		
g_4				e	
g_5					e

The object $g_1 * g_3$ is a new object, g_4 , and the column of g_1 is determined. Then, find the column of g_2 by means of the composition $*g_1 \circ *g_1$.

e	g_1	g_2	g_3	g_4	g_5
g_1	g_2	e			
g_2	e	g_1			
g_3	g_4	g_5	e		
g_4	g_5	g_3		e	
g_5	g_3	g_4			e

Then, use $|g_3| = 2$ to find

e	g_1	g_2	g_3	g_4	g_5
g_1	g_2	e			
g_2	e	g_1			
g_3	g_4	g_5	e		
g_4	g_5	g_3	g_2		
g_5	g_3	g_4	g_1		

Use $|g_3| = 2$ again, now to find

e	g_1	g_2	g_3	g_4	g_5
g_1	g_2	e	g_5		
g_2	e	g_1	g_4		
g_3	g_4	g_5	e		
g_4	g_5	g_3	g_2		
g_5	g_3	g_4	g_1		

It is trivial to find the columns of g_4, g_5 in terms of the rest of the columns, using associativity as usual.

$$\begin{array}{cccccc}
 e & g_1 & g_2 & g_3 & g_4 & g_5 \\
 g_1 & g_2 & e & g_5 & g_3 & g_4 \\
 g_2 & e & g_1 & g_4 & g_5 & g_3 \\
 g_3 & g_4 & g_5 & e & g_1 & g_2 \\
 g_4 & g_5 & g_3 & g_2 & e & g_1 \\
 g_5 & g_3 & g_4 & g_1 & g_2 & e
 \end{array} \tag{A1}$$

This is the direct product $\mathbb{Z}_2 \oplus \mathbb{Z}_3$. It is determined by the equations

$$\begin{aligned}
 g_1^2 &= g_2 \\
 g_1 * g_2 &= g_3^2 = g_4^2 = g_5^2 = e.
 \end{aligned}$$

Letters a, b, c, \dots and x_1, x_2, x_3, \dots are auxiliary variables in finding the canonical naming of groups. The first numerical value assigned is $e = 5$. Recall, the strategy is to assign the larger numbers first, by giving priority to the left-most columns. Within a column, priority is given to the objects of upper rows. Observe there are three objects of second order. One of these three objects, call it a , will be assigned the value 4. Then, whatever object may be chosen for b , there is a fourth object $a * b = x_1$. And, since $|a| = 2$ it is also true $a * x_1 = b$.

$$\begin{array}{cccc}
 e & a & b & x_1 \\
 a & e & & \\
 b & x_1 & & \\
 x_1 & b & &
 \end{array}$$

To maximize the representation, name $b = 3$ and $a * b = x_1 = 2$. That yields the numeric table

$$\begin{array}{cccc}
 5 & 4 & 3 & 2 \\
 4 & 5 & & \\
 3 & 2 & & \cdot \\
 2 & 3 & &
 \end{array}$$

So far, the only thing known about the canonical naming functions, is that $a = 4$ is one of the second order objects. If there were an object that commutes with a , it would be used as the object b . But, from (A1) it is clear there is no choice of b that commutes with a . That is to say, the second order objects of Δ_3 do not commute with any non trivial object. Therefore, new objects $c = b * a$ and $x_2 = a * c$, are added to the table as shown below

$$\begin{array}{cccccc}
 e & a & b & x_1 & c & x_2 \\
 a & e & c & & & \\
 b & x_1 & & & & \\
 x_1 & b & & & & \cdot \\
 c & x_2 & & & & \\
 x_2 & c & & & &
 \end{array}$$

Make $|b| = 2$, to maximize the representation. Now it is known a canonical naming function of this group must have $a = 4$ and $b = 3$ for two second order objects a, b . Also make $c = 1$ and $x_2 = 0$, to maximize the representation. Use $|b| = 2$ to find the rest of the column of b . The rest of the table is determined using associativity.

$$\begin{array}{cccccc}
 5 & 4 & 3 & 2 & 1 & 0 \\
 4 & 5 & 1 & 0 & 3 & 2 \\
 3 & 2 & 5 & 4 & 0 & 1 \\
 2 & 3 & 0 & 1 & 5 & 4 \\
 1 & 0 & 4 & 5 & 2 & 3 \\
 0 & 1 & 2 & 3 & 4 & 5
 \end{array}$$

To obtain a canonical naming function make $a = 4$, $b = 3$ for two objects of order 2. Obviously, g_3, g_4, g_5 are equivalent objects; two of these have to be chosen to take the values of 4 and 3. This implies g_3, g_4, g_5 are equivalent. The object $a * b$ is assigned the value $x_1 = 2$. Then $b * a = c = 1$ and $a * c = x_2 = 0$. The objects g_2, g_3 are equivalent. There is a total of six possible canonical naming functions.

$$\begin{array}{lll} (e, g_3, g_4, g_2, g_1, g_5) & (e, g_4, g_3, g_1, g_2, g_5) & (e, g_5, g_3, g_2, g_1, g_4) \\ (e, g_3, g_5, g_1, g_2, g_4) & (e, g_4, g_5, g_2, g_1, g_3) & (e, g_5, g_4, g_1, g_2, g_3) \end{array}$$

The group has a total of six automorphisms, given by the six canonical naming functions. The group is shown in block form, but the blocks are not cosets of a normal subgroup (even though Δ_6 has a normal subgroup). The canonical block form is composed of four 3×3 blocks, and there are two types of blocks. The first type of block has objects in $A = \{1, 2, 3, 4, 5\}$ while the second type of block has objects in $B = \{0, 1, 2, 3, 4\}$. Blocks A_1 and A_2 are located in the upper left corner and lower right corner, respectively. Blocks B_1 and B_2 are in the upper right hand and lower left hand, respectively. This group has canonical representation

$$\begin{aligned} N_{\Delta_3} = & 2^{2^{11}+2} \left(2^{(2^{11}+2^{12})+2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1} \right) \\ & + 2^{2^9+2} \left(2^{(2^{11}+2^{10})+2(2^9+2^{12})+2(2^7+2^6)+2(2^5+2^8)+2(2^3+2^2)+2(2^1+2^4)+1} \right) \\ & + 2^{2^7+2} \left(2^{(2^{11}+2^8)+2(2^9+2^4)+2(2^7+2^{12})+2(2^5+2^2)+2(2^3+2^{10})+2(2^1+2^6)+1} \right) \\ & + 2^{2^5+2} \left(2^{(2^{11}+2^6)+2(2^9+2^2)+2(2^7+2^{10})+2(2^5+2^4)+2(2^3+2^{12})+2(2^1+2^8)+1} \right) \\ & + 2^{2^3+2} \left(2^{(2^{11}+2^4)+2(2^9+2^8)+2(2^7+2^2)+2(2^5+2^{12})+2(2^3+2^6)+2(2^1+2^{10})+1} \right) \\ & + 2^{2^1+2} \left(2^{(2^{11}+2^2)+2(2^9+2^6)+2(2^7+2^4)+2(2^5+2^{10})+2(2^3+2^8)+2(2^1+2^{12})+1} \right). \end{aligned}$$

Cyclic Group \mathbb{Z}_6 . Now consider the case with four objects of order 4, and one object of order 2.

$$\begin{array}{cccccc} e & g_1 & g_2 & g_3 & g_4 & g_5 \\ g_1 & e & & & & \\ g_2 & & g_3 & e & & \\ g_3 & & e & g_2 & & \\ g_4 & & & & & \\ g_5 & & & & & \end{array}$$

Without loss of generality, make $g_1 * g_2 = g_4$.

$$\begin{array}{cccccc} e & g_1 & g_2 & g_3 & g_4 & g_5 \\ g_1 & e & & & & \\ g_2 & g_4 & g_3 & e & & \\ g_3 & g_5 & e & g_2 & & \\ g_4 & & & & & \\ g_5 & & & & & \end{array}$$

Using $|g_1| = 2$, one finds

e	g_1	g_2	g_3	g_4	g_5
g_1	e				
g_2	g_4	g_3	e		
g_3	g_5	e	g_2		
g_4	g_2				
g_5	g_3				

Now use $|g_2| = |g_3| = 3$ to find

e	g_1	g_2	g_3	g_4	g_5
g_1	e				
g_2	g_4	g_3	e	g_5	g_1
g_3	g_5	e	g_2	g_1	g_4
g_4	g_2				
g_5	g_3				

It is the case that $|g_4| = |g_5| \neq 2$, so the only option is $g_4^2 = g_3$ and $g_5^2 = g_2$.

e	g_1	g_2	g_3	g_4	g_5
g_1	e				
g_2	g_4	g_3	e	g_5	g_1
g_3	g_5	e	g_2	g_1	g_4
g_4	g_2			g_3	
g_5	g_3				g_2

It is easy to see that $|g_4| = |g_5| = 6$. It is concluded there is no group $|G| = 4$ with four objects of order 2. The table is determined and the cyclic group is obtained.

e	g_1	g_2	g_3	g_4	g_5
g_1	e	g_4	g_5	g_2	g_3
g_2	g_4	g_3	e	g_5	g_1
g_3	g_5	e	g_2	g_1	g_4
g_4	g_2	g_5	g_1	g_3	e
g_5	g_3	g_1	g_4	e	g_2

(A2)

The cyclic group \mathbb{Z}_6 is determined by $|G| = 6$ and

$$\begin{aligned} g_1^2 &= e \\ g_2^2 = g_3^2 &= g_4 \\ g_1 * g_2 &= g_3 \\ g_4^2 &= g_2. \end{aligned}$$

To find the canonical naming functions, use a, b, c, \dots and x_1, x_2, x_3, \dots as auxiliary variables. Start naming $e = 5$. There is only one second order object, so $g_1 = a = 4$. Add an object $b \neq g_1$. Whatever object is chosen for b , there is another object $a * b = x_1$. The group is commutative, so $b * a = x_1$. Since $|a| = 2$, it can be verified that $a * x_1 = b$. Commutativity gives $x_1 * a = b$.

e	a	b	x_1
a	e	x_1	b
b	x_1		
x_1	b		

In order to maximize the representation, name $b = 3$ and $a * b = x_1 = 2$. But, it is still not known what object of the group will be assigned to $b = 3$. The possible naming functions are

$$\begin{array}{cccc} (e, g_1, g_2, g_4, g_3, g_5) & (e, g_1, g_3, g_5, g_2, g_4) & (e, g_1, g_4, g_2, g_3, g_5) & (e, g_1, g_5, g_3, g_2, g_4) \\ (e, g_1, g_2, g_4, g_5, g_3) & (e, g_1, g_3, g_5, g_4, g_2) & (e, g_1, g_4, g_2, g_5, g_3) & (e, g_1, g_5, g_3, g_4, g_2). \end{array}$$

Whatever object b may be, b^2 is a new object c . Then, the operation $a * c$ is a new object x_2 . Consequently, $b * x_1 = x_1 * b = x_2$ and $x_1^2 = c$. To maximize the representation, make $c = 1$ and $x_2 = 0$.

$$\begin{array}{cccccc} e & a & b & x_1 & c & x_2 \\ a & e & x_1 & b & x_2 & c \\ b & x_1 & c & x_2 & & \\ x_1 & b & x_2 & c & & \\ c & x_2 & & & & \\ x_2 & c & & & & \end{array}$$

Some of the naming functions can be eliminated. Keep only those such that the square of the third component is equal to the fifth component ($b^2 = c$). Notice, only the objects g_2, g_3 are the square of some other object. The naming functions that satisfy these conditions are reduced to four.

$$\begin{array}{l} (e, g_1, g_2, g_4, g_3, g_5) \\ (e, g_1, g_3, g_5, g_2, g_4) \\ (e, g_1, g_4, g_2, g_3, g_5) \\ (e, g_1, g_5, g_3, g_2, g_4) \end{array}$$

Any of the naming functions above, gives the table below.

$$\begin{array}{cccccc} e & a & b & x_1 & c & x_2 \\ a & e & x_1 & b & x_2 & c \\ b & x_1 & c & x_2 & & \\ x_1 & b & x_2 & c & & \\ c & x_2 & & & & \\ x_2 & c & & & & \end{array}$$

No more operations can be determined with the information available. A choice must be made for b, c , so that $b * c = e$ or $b * c = a$. Choosing them so $b * c = e$ maximizes the representation. The four candidate naming functions above satisfy this condition, so the candidate naming functions have not been reduced by this. However, the table is now

$$\begin{array}{cccccc} e & a & b & x_1 & c & x_2 \\ a & e & x_1 & b & x_2 & c \\ b & x_1 & c & x_2 & e & a \\ x_1 & b & x_2 & c & a & e \\ c & x_2 & e & a & & \\ x_2 & c & a & e & & \end{array}.$$

Next, focus on c^2 . Notice that two of the four naming functions satisfy $c^2 = x_1$. The other two naming functions satisfy $c^2 = b$. The latter two maximize the representation. The two canonical naming functions are $(e, g_1, g_2, g_4, g_3, g_5)$ and $(e, g_1, g_3, g_5, g_2, g_4)$. The cyclic group \mathbb{Z}_6 has a total of two automorphisms. Take $A = (e, g_1, g_3, g_5, g_2, g_4)$. The non trivial automorphism is the function ϕ with components $e \mapsto e, g_1 \mapsto g_1, g_2 \mapsto g_3, g_3 \mapsto g_2,$

$g_4 \mapsto g_5, g_5 \mapsto g_4$. Taking $A = (e, g_1, g_2, g_4, g_3, g_5)$ and $B = (e, g_1, g_3, g_5, g_2, g_4)$, gives the same non trivial automorphism ϕ . The numeric table givrn by these naming functions is

5	4	3	2	1	0
4	5	2	3	0	1
3	2	1	0	5	4
2	3	0	1	4	5
1	0	5	4	3	2
0	1	4	5	2	3

The 2×2 block on the upper left hand corner is the normal subgroup $N = \mathbb{Z}_2$. The table is made up of nine 2×2 blocks that are the cosets N, bN and b^2N , for $b \in \{g_2, g_3\}$. These coset blocks form the group \mathbb{Z}_3 . The canonical table above is written as

N	bN	b^2N
bN	b^2N	N
b^2N	N	bN

The canonical naming table gives the additional information that $\mathbb{Z}_6/\mathbb{Z}_2 = \mathbb{Z}_3$. The canonical representation of the cyclic group is

$$\begin{aligned}
 N_{\mathbb{Z}_6} = & 2^{2^{11}+2} \left(2^{(2^{11}+2^{12})+2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1} \right) \\
 & + 2^{2^9+2} \left(2^{(2^{11}+2^{10})+2(2^9+2^{12})+2(2^7+2^6)+2(2^5+2^8)+2(2^3+2^2)+2(2^1+2^4)+1} \right) \\
 & + 2^{2^7+2} \left(2^{(2^{11}+2^8)+2(2^9+2^6)+2(2^7+2^4)+2(2^5+2^2)+2(2^3+2^{12})+2(2^1+2^{10})+1} \right) \\
 & + 2^{2^5+2} \left(2^{(2^{11}+2^6)+2(2^9+2^8)+2(2^7+2^2)+2(2^5+2^4)+2(2^3+2^{10})+2(2^1+2^{12})+1} \right) \\
 & + 2^{2^3+2} \left(2^{(2^{11}+2^4)+2(2^9+2^2)+2(2^7+2^{12})+2(2^5+2^{10})+2(2^3+2^8)+2(2^1+2^6)+1} \right) \\
 & + 2^{2^1+2} \left(2^{(2^{11}+2^2)+2(2^9+2^4)+2(2^7+2^{10})+2(2^5+2^{12})+2(2^3+2^6)+2(2^1+2^8)+1} \right) .
 \end{aligned}$$

Up to this point, there has not been any difficulty in finding the canonical naming and representation of groups. The first groups are ordered

$$\begin{aligned}
 G_0 &= \mathbb{Z}_1 \\
 G_1 &= \mathbb{Z}_2 \\
 G_2 &= \mathbb{Z}_3 \\
 G_3 &= \mathbb{Z}_4 \\
 G_4 &= \mathbb{Z}_2 \oplus \mathbb{Z}_2 \\
 G_5 &= \mathbb{Z}_5 \\
 G_6 &= \mathbb{Z}_6 \\
 G_7 &= \mathbb{Z}_2 \oplus \mathbb{Z}_3.
 \end{aligned}$$

The first step in finding the canonical naming function is to identify the objects of smallest order. By now it is easy to find the canonical table and representation of \mathbb{Z}_7 (see \mathbb{Z}_5). This is the next group in order, $G_8 = \mathbb{Z}_7$.

Appendix 3 $|G| = 8$

To find groups of eight objects, observe the possible orders of the objects are the divisors of 8. Particularly, there exists at least one object of order 2. There can be a multiple of two, $2i$, objects of order 4, and a multiple of four, $4j$, many objects of order 8. All four groups of eight objects will be found. Each group has a canonical naming function, obtained from the numeric table, a minimal independent set of equations that defines the group, and canonical representation. Then, the canonical representations of these groups are compared to find the order $G_9 < G_{10} < G_{11} < G_{12} < G_{13}$.

Direct Product $\mathbb{Z}_2 \oplus \mathbb{Z}_2 \oplus \mathbb{Z}_2$. Take the simplest case first, and then it will be clear how things can be complicated little by little. The simplest case is to consider all objects of order 2 (make $i = j = 0$). Additionally, suppose the group is commutative. With maximization in mind, this gives the table

e	g_1	g_2	g_3	g_4	g_5	g_6	g_7
g_1	e	g_3	g_2	g_5	g_4	g_7	g_6
g_2	g_3	e	g_1				
g_3	g_2	g_1	e				
g_4	g_5			e	g_1		
g_5	g_4			g_1	e		
g_6	g_7					e	g_1
g_7	g_6					g_1	e

It is easy to see $g_2 * g_4 \notin \{e, g_1, g_2, g_3, g_4, g_5\}$. Suppose, without loss of generality, $g_2 * g_4 = g_6$. This determines the rest of the column of g_2 . Then, use $g_2 * g_4 = g_4 * g_2$ and $g_2 * g_6 = g_6 * g_2$ to find the third row. Then it is possible to find the fourth column and fourth row, using the associative property. For example, use $g_6 * g_2 = g_4$ to find $g_4 * g_3 = g_6 * (g_2 * g_3) = g_6 * g_1 = g_7$. Finally, use $g_3 * g_5 = g_6$ to find $g_6 * g_4 = g_3 * (g_5 * g_4) = g_3 * g_1 = g_2$.

e	g_1	g_2	g_3	g_4	g_5	g_6	g_7
g_1	e	g_3	g_2	g_5	g_4	g_7	g_6
g_2	g_3	e	g_1	g_6	g_7	g_4	g_5
g_3	g_2	g_1	e	g_7	g_6	g_5	g_4
g_4	g_5	g_6	g_7	e	g_1	g_2	g_3
g_5	g_4	g_7	g_6	g_1	e	g_3	g_2
g_6	g_7	g_4	g_5	g_2	g_3	e	g_1
g_7	g_6	g_5	g_4	g_3	g_2	g_1	e

(A3)

This determines the group $\mathbb{Z}_2^3 = \mathbb{Z}_2 \oplus \mathbb{Z}_2 \oplus \mathbb{Z}_2$. This group table is already in canonical block form. Again, the special block form of cosets of $N_1 = \mathbb{Z}_2$ is seen. The expression $\mathbb{Z}_8/N = \mathbb{Z}_4$ is given in the table, because there are sixteen 2×2 blocks, $N_1, g_2N_1, g_4N_1, g_6N_1$, that form \mathbb{Z}_4 .

N_1	g_2N_1	g_4N_1	g_6N_1
g_2N_1	N_1	g_6N_1	g_4N_1
g_4N_1	g_6N_1	N_1	g_2N_1
g_6N_1	g_4N_1	g_2N_1	N_1

The group \mathbb{Z}_4 has normal subgroup $N_2 = \mathbb{Z}_2$, and $\mathbb{Z}_4/\mathbb{Z}_2 = \mathbb{Z}_2$. A third expression of group quotients can be observed. Table (A3) also gives the expression $\mathbb{Z}_8/\mathbb{Z}_4 = \mathbb{Z}_2$ because there are four 4×4 blocks forming the group \mathbb{Z}_2 ; these blocks are the cosets of $N_3 = \mathbb{Z}_4$,

$$\begin{array}{cc} N_3 & cN_3 \\ cN_3 & N_3 \end{array}.$$

To determine this group, seven objects of order 2 are required. Additionally, a commutative object, g_1 , is needed. The following equations determine the group.

$$e = g_1^2 = g_2^2 = g_3^2 = g_4^2 = g_5^2 = g_6^2 = g_7^2$$

$$g_1 * g = g * g_1, \quad g \in \mathbb{Z}_2^3.$$

There is a total of one hundred and sixty eight distinct automorphisms of \mathbb{Z}_2^3 , given by the canonical naming functions. Assign $e = 7$ for the identity element, and $a = 6$ for any non trivial element of the group. Then, assign $b = 5$ to a second non trivial element. To maximize representation, assign $a * b = x_1 = 4$. Next, choose a third object to assign to $c = 3$, and $a * c = x_2 = 2$.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	e	a				
x_1	b	a	e				
c	x_2			e	a		
x_2	c			a	e		
d	x_3					e	a
x_3	d					a	e

Finally, make $b * c = d = 1$ and $a * d = x_3 = 0$. This determines the rest of the table. The first object, a , is chosen from seven different possible choices. The object b is chosen from a total of six options. Finally, c is taken from a total of four different options. The numeric table, given by these canonical naming functions is

7	6	5	4	3	2	1	0
6	7	4	5	2	3	0	1
5	4	7	6	1	0	3	2
4	5	6	7	0	1	2	3
3	2	1	0	7	6	5	4
2	3	0	1	6	7	4	5
1	0	3	2	5	4	7	6
0	1	2	3	4	5	6	7

and the canonical representation is

$$N_{\mathbb{Z}_2^3} = 2^{2^{15}+2} \left(2^{2^{(2^{15}+2^{16})+2^{(2^{13}+2^{14})+2^{(2^{11}+2^{12})+2^{(2^9+2^{10})+2^{(2^7+2^8)+2^{(2^5+2^6)+2^{(2^3+2^4)+2^{(2^1+2^2)+1}}}}}}}} \right)$$

$$+ 2^{2^{13}+2} \left(2^{2^{(2^{15}+2^{14})+2^{(2^{13}+2^{16})+2^{(2^{11}+2^{10})+2^{(2^9+2^{12})+2^{(2^7+2^6)+2^{(2^5+2^8)+2^{(2^3+2^2)+2^{(2^1+2^4)+1}}}}}}}} \right)$$

$$+ 2^{2^{11}+2} \left(2^{2^{(2^{15}+2^{12})+2^{(2^{13}+2^{10})+2^{(2^{11}+2^{16})+2^{(2^9+2^{14})+2^{(2^7+2^4)+2^{(2^5+2^2)+2^{(2^3+2^8)+2^{(2^1+2^6)+1}}}}}}}} \right)$$

$$+ 2^{2^9+2} \left(2^{2^{(2^{15}+2^{10})+2^{(2^{13}+2^{12})+2^{(2^{11}+2^{14})+2^{(2^9+2^{16})+2^{(2^7+2^2)+2^{(2^5+2^4)+2^{(2^3+2^6)+2^{(2^1+2^8)+1}}}}}}}} \right)$$

$$+ 2^{2^7+2} \left(2^{2^{(2^{15}+2^8)+2^{(2^{13}+2^6)+2^{(2^{11}+2^4)+2^{(2^9+2^2)+2^{(2^7+2^{16})+2^{(2^5+2^{14})+2^{(2^3+2^{12})+2^{(2^1+2^{10})+1}}}}}}}} \right)$$

$$+ 2^{2^5+2} \left(2^{2^{(2^{15}+2^6)+2^{(2^{13}+2^8)+2^{(2^{11}+2^2)+2^{(2^9+2^4)+2^{(2^7+2^{14})+2^{(2^5+2^{16})+2^{(2^3+2^{10})+2^{(2^1+2^{12})+1}}}}}}}} \right)$$

$$+ 2^{2^3+2} \left(2^{2^{(2^{15}+2^4)+2^{(2^{13}+2^2)+2^{(2^{11}+2^8)+2^{(2^9+2^6)+2^{(2^7+2^{12})+2^{(2^5+2^{10})+2^{(2^3+2^{16})+2^{(2^1+2^{14})+1}}}}}}}} \right)$$

$$+ 2^{2^1+2} \left(2^{2^{(2^{15}+2^2)+2^{(2^{13}+2^4)+2^{(2^{11}+2^6)+2^{(2^9+2^8)+2^{(2^7+2^{10})+2^{(2^5+2^{12})+2^{(2^3+2^{14})+2^{(2^1+2^{16})+1}}}}}}}} \right).$$

A non abelian group with all objects of order 2 does not exist. If $c * a = d$, then $d * a = c$ because $|a| = 2$. Since $|d| = 2$ it is also true $d * c = a$. On the other hand, $a * c = x_2$ and $|c| = 2$ imply $x_2 * c = a$. This is a contradiction with the definition of group.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	d	x_3	c	x_2
b	x_1	e	a				
x_1	b	a	e				
c	x_2			e	a	a	
x_2	c				e		
d	x_3					e	
x_3	d						e

The contradiction does not depend on the first four objects e, a, b, x_1 . This means that any non abelian group of eight objects, must also have objects of order 4 or 8. In particular, the group \mathbb{Z}_2^3 , above, is the only group of eight objects with all non trivial elements of order 2. The commutative condition determined the group. Commutativity of one non trivial element implies commutativity on all the elements of the group.

Dihedral Group D_8 . Now consider groups with elements of orders 2 and 4. Only a multiple of $2 = \phi(4)$, many objects of order 4 are possible. First, consider the case with two objects of order 4, and five objects of second order. Let a, b, x_1, c, x_2 be the objects of order 2, and let d, x_3 the objects of order 4.

e	a	b	x_1	c	x_2	d	x_3
a	e						
b	x_1	e					
x_1	b		e				
c	x_2			e			
x_2	c				e		
d	x_3					a	e
x_3	d					e	a

Since $|b| = |x_1| = |c| = |x_2| = 2$, then $x_1 * b = b * x_1 = x_2 * c = c * x_2 = a$.

e	a	b	x_1	c	x_2	d	x_3
a	e						
b	x_1	e	a				
x_1	b	a	e				
c	x_2			e	a		
x_2	c			a	e		
d	x_3					a	e
x_3	d					e	a

Now, $|b| = |x_1| = |c| = |x_2| = 2$ implies $b * a = x_1, x_1 * a = b, c * a = x_2, x_2 * a = c$, respectively. Then, $d * a = x_3$ and $x_3 * a = d$. Notice a block form is starting to appear in the table for $K(4)$. There are 2×2 blocks forming the Klein group. Suppose, without loss of generality, $b * c = d$.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	e	a				
x_1	b	a	e				
c	x_2	d	x_3	e	a		
x_2	c	x_3	d	a	e		
d	x_3					a	e
x_3	d					e	a

The rest of the table is determined. Find $b * d = c$, and $d * c = b$.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	e	a				
x_1	b	a	e				
c	x_2	d	x_3	e	a	b	x_1
x_2	c	x_3	d	a	e	x_1	b
d	x_3	c	x_2			a	e
x_3	d	x_2	c			e	a

Next use $c = b * d$ to find $c * d = b * (d * d) = b * a = x_1$.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	e	a				
x_1	b	a	e				
c	x_2	d	x_3	e	a	b	x_1
x_2	c	x_3	d	a	e	x_1	b
d	x_3	c	x_2	x_1	b	a	e
x_3	d	x_2	c	b	x_1	e	a

The rest of the table is determined similarly. For example, $|c| = 2$ implies $c * b = x_3$.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	e	a	x_3	d	c	x_2
x_1	b	a	e	d	x_3	x_2	c
c	x_2	d	x_3	e	a	b	x_1
x_2	c	x_3	d	a	e	x_1	b
d	x_3	c	x_2	x_1	b	a	e
x_3	d	x_2	c	b	x_1	e	a

This is the Dihedral group, D_8 , defined by $|G| = 8$ and the set of equations

$$e = a^2 = b^2 = x_1^2 = c^2 = x_2^2 \\ d^2 = a.$$

It is the only group $|G| = 8$, with exactly two objects of order 4, and five objects of order 2. Notice that the set of equations only mentions seven different objects. The eighth object is $a * d$, and it is of order 4. To find the canonical naming function of this group, write the group with non generic symbols.

e	g_1	g_2	g_3	g_4	g_5	g_6	g_7
g_1	e	g_3	g_2	g_5	g_4	g_7	g_6
g_2	g_3	g_1	e	g_7	g_6	g_4	g_5
g_3	g_2	e	g_1	g_6	g_7	g_5	g_4
g_4	g_5	g_6	g_7	e	g_1	g_2	g_3
g_5	g_4	g_7	g_6	g_1	e	g_3	g_2
g_6	g_7	g_5	g_4	g_3	g_2	e	g_1
g_7	g_6	g_4	g_5	g_2	g_3	g_1	e

(A4)

Now, use the letters $a, b, \dots, x_1, x_2, \dots$ as auxiliary variables to find the canonical naming. Avoid confusion with the fact that the same symbols $a, b, \dots, x_1, x_2, \dots$ have just been used as auxiliary variables to find the group. Table (A4) will be the reference for D_8 . Start with $e = 7$, and an arbitrary object, $a = 6$, of order 2. Add an object $b = 5$. To

maximize the representation, make $x_1 = a * b = b * a = 4$. Put simply, one must choose two objects, a, b , that satisfy $e = a^2$ and $a * b = b * a$. There are ten options of ordered pairs of D_8 that satisfy these relations. For example, g_7 is a second order object and it commutes with g_6 . Also, g_1 is a second order object and it commutes with g_2 . Furthermore, an element b can be found such that $|b| = 2$, maximizing the representation. There are six options to do this. The objects g_4, g_5 commute, as do g_6, g_7 and they are all second order objects. Also, notice g_1 commutes with each of them. Therefore, any of these objects can take the place of a , for now. Add another object to the table, say $c = 3$, and consequently $x_2 = a * c = 2$. Then, add another object $d = 1$, for the product $b * c = d$, and $x_3 = a * d = 0$.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b				
b	x_1	e	a				
x_1	b	a	e				
c	x_2	d	x_3				
x_2	c	x_3	d				
d	x_3	c	x_2				
x_3	d	x_2	c				

In order to maximize the representation, find c that commutes with a . This implies a also commutes with $x_2 = a * c$. The only object that commutes with at least four objects is g_1 . Therefore, $a = g_1$. The possible canonical naming functions have been reduced to a total of sixteen possible naming functions. Choose b from four different objects, $\{g_4, g_5, g_6, g_7\}$, and then c can be chosen from four different objects.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	e	a				
x_1	b	a	e				
c	x_2	d	x_3				
x_2	c	x_3	d				
d	x_3	c	x_2				
x_3	d	x_2	c				

None of the choices of naming functions will have $b * c = c * b$. This is because the four options for assigning b , which are g_4, g_5, g_6, g_7 , only commute with g_1 and $a * b = x_1$. For example, g_4 only commutes with g_1 and $g_5 = g_1 * g_4$, etc. So far, the canonical block form is

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	e	a	x_3	d		
x_1	b	a	e	d	x_3		
c	x_2	d	x_3				
x_2	c	x_3	d				
d	x_3	c	x_2				
x_3	d	x_2	c				

Notice that in eight of the sixteen possible naming functions, there are eight that satisfy $c^2 = e$. The other eight functions assign c to g_2 or g_3 . To maximize the representation choose the first eight naming functions; assign c to a second order object.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	e	a	x_3	d		
x_1	b	a	e	d	x_3		
c	x_2	d	x_3	e	a		
x_2	c	x_3	d	a	e		
d	x_3						
x_3	d						

The rest of the table is determined. There is a total of eight canonical naming functions. Choose b from the list $\{g_4, g_5, g_6, g_7\}$, and make $x_1 = g_1 * b$. Then choose c from the remaining two objects of that list. The objects g_4, g_5 are equivalent, and g_6, g_7 are equivalent. The order 4 objects g_2, g_3 are equivalent. The canonical naming functions are

$$\begin{array}{llll}
 (e, g_1, g_4, g_5, g_6, g_7, g_3, g_2) & (e, g_1, g_5, g_4, g_6, g_7, g_2, g_3) & (e, g_1, g_6, g_7, g_4, g_5, g_2, g_3) & (e, g_1, g_7, g_6, g_4, g_5, g_3, g_2) \\
 (e, g_1, g_4, g_5, g_7, g_6, g_2, g_3) & (e, g_1, g_5, g_4, g_7, g_6, g_3, g_2) & (e, g_1, g_6, g_7, g_5, g_4, g_3, g_2) & (e, g_1, g_7, g_6, g_5, g_4, g_2, g_3)
 \end{array}$$

The numeric table is

7	6	5	4	3	2	1	0
6	7	4	5	2	3	0	1
5	4	7	6	0	1	2	3
4	5	6	7	1	0	3	2
3	2	1	0	7	6	5	4
2	3	0	1	6	7	4	5
1	0	3	2	4	5	6	7
0	1	2	3	5	4	7	6

and the canonical representation is

$$\begin{aligned}
 N_{D_8} = & 2^{2^{15}+2} \left(2^{(2^{15}+2^{16})+2(2^{13}+2^{14})+2(2^{11}+2^{12})+2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1} \right) \\
 & + 2^{2^{13}+2} \left(2^{(2^{15}+2^{14})+2(2^{13}+2^{16})+2(2^{11}+2^{10})+2(2^9+2^{12})+2(2^7+2^6)+2(2^5+2^8)+2(2^3+2^2)+2(2^1+2^4)+1} \right) \\
 & + 2^{2^{11}+2} \left(2^{(2^{15}+2^{12})+2(2^{13}+2^{10})+2(2^{11}+2^{16})+2(2^9+2^{14})+2(2^7+2^4)+2(2^5+2^2)+2(2^3+2^8)+2(2^1+2^6)+1} \right) \\
 & + 2^{2^9+2} \left(2^{(2^{15}+2^{10})+2(2^{13}+2^{12})+2(2^{11}+2^{14})+2(2^9+2^{16})+2(2^7+2^2)+2(2^5+2^4)+2(2^3+2^6)+2(2^1+2^8)+1} \right) \\
 & + 2^{2^7+2} \left(2^{(2^{15}+2^8)+2(2^{13}+2^6)+2(2^{11}+2^2)+2(2^9+2^4)+2(2^7+2^{16})+2(2^5+2^{14})+2(2^3+2^{10})+2(2^1+2^{12})+1} \right) \\
 & + 2^{2^5+2} \left(2^{(2^{15}+2^6)+2(2^{13}+2^8)+2(2^{11}+2^4)+2(2^9+2^2)+2(2^7+2^{14})+2(2^5+2^{16})+2(2^3+2^{12})+2(2^1+2^{10})+1} \right) \\
 & + 2^{2^3+2} \left(2^{(2^{15}+2^4)+2(2^{13}+2^2)+2(2^{11}+2^6)+2(2^9+2^8)+2(2^7+2^{12})+2(2^5+2^{10})+2(2^3+2^{14})+2(2^1+2^{16})+1} \right) \\
 & + 2^{2^1+2} \left(2^{(2^{15}+2^2)+2(2^{13}+2^4)+2(2^{11}+2^8)+2(2^9+2^6)+2(2^7+2^{10})+2(2^5+2^{12})+2(2^3+2^{16})+2(2^1+2^{14})+1} \right) .
 \end{aligned}$$

Direct Product $\mathbb{Z}_2 \oplus \mathbb{Z}_4$. Now consider groups with four objects of order 4, and three objects of order 2. Let a any object of order 4, so that $a^2 = b$ is a new object, as is $a^3 = c$.

e	a	x_1	x_2	b	x_3	x_4	x_5
a	x_1	x_2	e				
x_1	x_2	e	a				
x_2	e	a	x_1				
b							
x_3							
x_4							
x_5							

The column of a can be completed. Let b an object not in $\{e, a, x_1, x_2\}$. The expression $a * b = x_3$ holds for an element x_3 that is not in $\{e, a, x_1, x_2, b\}$. The columns of x_1 and x_2 can be completed.

e	a	x_1	x_2	b	x_3	x_4	x_5
a	x_1	x_2	e				
x_1	x_2	e	a				
x_2	e	a	x_1				
b	x_3	x_4	x_5				
x_3	x_4	x_5	b				
x_4	x_5	b	x_3				
x_5	b	x_3	x_4				

Choose b such that it has order $|b| = 2$. This gives the row of b .

e	a	x_1	x_2	b	x_3	x_4	x_5
a	x_1	x_2	e				
x_1	x_2	e	a				
x_2	e	a	x_1				
b	x_3	x_4	x_5	e	a	x_1	x_2
x_3	x_4	x_5	b				
x_4	x_5	b	x_3				
x_5	b	x_3	x_4				

Consider two different cases; the cases where b, x_3 commute or not. Supposing they do not commute leads to contradiction. It is a good exercise to find the contradiction in the least number of steps. For the commutative case, the table is determined.

e	a	x_1	x_2	b	x_3	x_4	x_5
a	x_1	x_2	e	x_3	x_4	x_5	b
x_1	x_2	e	a	x_4	x_5	b	x_3
x_2	e	a	x_1	x_5	b	x_3	x_4
b	x_3	x_4	x_5	e	a	x_1	x_2
x_3	x_4	x_5	b	a	x_1	x_2	e
x_4	x_5	b	x_3	x_1	x_2	e	a
x_5	b	x_3	x_4	x_2	e	a	x_1

This is the direct product group $\mathbb{Z}_2 \oplus \mathbb{Z}_4$. To define this group, an object of order 4 is required, as given by the equations $a^2 = x_1$, $a * x_1 = x_2$, $a * x_2 = e$. Then, a second order object, b , that commutes with $x_3 = a * b$. These conditions form the system of equations

$$\begin{aligned}a^2 &= x_1 \\a^3 &= x_2 \\a * x_2 &= b^2 = e \\a * b &= x_3 \\b * x_3 &= x_3 * b\end{aligned}$$

To find the canonical naming functions, write the table in terms of g_i .

$$\begin{array}{cccccccc}e & g_1 & g_2 & g_3 & g_4 & g_5 & g_6 & g_7 \\g_1 & g_2 & g_3 & e & g_5 & g_6 & g_7 & g_4 \\g_2 & g_3 & e & g_1 & g_6 & g_7 & g_4 & g_5 \\g_3 & e & g_1 & g_2 & g_7 & g_4 & g_5 & g_6 \\g_4 & g_5 & g_6 & g_7 & e & g_1 & g_2 & g_3 \\g_5 & g_6 & g_7 & g_4 & g_1 & g_2 & g_3 & e \\g_6 & g_7 & g_4 & g_5 & g_2 & g_3 & e & g_1 \\g_7 & g_4 & g_5 & g_6 & g_3 & e & g_1 & g_2\end{array} \quad (A5)$$

Begin by assigning $e = 7$, and $a = 6$ for some second order object a . Choose an arbitrary object $b = 5$, and make $a * b = x_1 = 4$. The group is commutative. Choose b of second order. This gives the table of $K(4)$. Maximization of the representation is guaranteed thus far.

$$\begin{array}{cccc}e & a & b & x_1 \\a & e & x_1 & b \\b & x_1 & e & a \\x_1 & b & a & e\end{array}.$$

Add another arbitrary object from the remaining elements; $c = 3$, and $a * c = x_2 = 2$. The objects that c can be chosen from are g_1, g_3, g_5, g_7 . Then, the value of 1 is assigned to the element $b * c = c * b = d = 1$, and the smallest value is assigned to $x_3 = a * d = 0$.

$$\begin{array}{cccccccc}e & a & b & x_1 & c & x_2 & d & x_3 \\a & e & x_1 & b & x_2 & c & x_3 & d \\b & x_1 & e & a & d & x_3 & c & x_2 \\x_1 & b & a & e & x_3 & d & x_2 & c \\c & x_2 & d & x_3 & & & & \\x_2 & c & x_3 & d & & & & \\d & x_3 & c & x_2 & & & & \\x_3 & d & x_2 & c & & & & \end{array}$$

To continue maximizing the representation, choose a so that it is the square of some object, $c^2 = a$. Therefore, $g_2 = a = 7$ because g_2 is the only non trivial element that is square of another group element. This determines the table. To find a canonical naming function choose b from two possible choices, g_4, g_6 . Then choose c from four possible choices, g_1, g_3, g_5, g_7 . There is a total of eight canonical naming functions defining eight automorphisms of $\mathbb{Z}_2 \oplus \mathbb{Z}_4$.

$$\begin{array}{llll}(e, g_2, g_4, g_6, g_1, g_3, g_5, g_7) & (e, g_2, g_4, g_6, g_3, g_1, g_7, g_5) & (e, g_2, g_4, g_6, g_5, g_7, g_1, g_3) & (e, g_2, g_4, g_6, g_7, g_5, g_3, g_1) \\(e, g_2, g_6, g_4, g_1, g_3, g_7, g_5) & (e, g_2, g_6, g_4, g_3, g_1, g_5, g_7) & (e, g_2, g_6, g_4, g_5, g_7, g_3, g_1) & (e, g_2, g_6, g_4, g_7, g_5, g_1, g_3)\end{array}$$

These naming functions give the numeric table

7	6	5	4	3	2	1	0
6	7	4	5	2	3	0	1
5	4	7	6	1	0	3	2
4	5	6	7	0	1	2	3
3	2	1	0	6	7	4	5
2	3	0	1	7	6	5	4
1	0	3	2	4	5	6	7
0	1	2	3	5	4	7	6

with canonical representation

$$\begin{aligned}
 N_{\mathbb{Z}_2 \oplus \mathbb{Z}_4} = & 2^{2^{15}+2} \left(2^{(2^{15}+2^{16})+2(2^{13}+2^{14})+2(2^{11}+2^{12})+2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1} \right) \\
 & + 2^{2^{13}+2} \left(2^{(2^{15}+2^{14})+2(2^{13}+2^{16})+2(2^{11}+2^{10})+2(2^9+2^{12})+2(2^7+2^6)+2(2^5+2^8)+2(2^3+2^2)+2(2^1+2^4)+1} \right) \\
 & + 2^{2^{11}+2} \left(2^{(2^{15}+2^{12})+2(2^{13}+2^{10})+2(2^{11}+2^{16})+2(2^9+2^{14})+2(2^7+2^4)+2(2^5+2^2)+2(2^3+2^8)+2(2^1+2^6)+1} \right) \\
 & + 2^{2^9+2} \left(2^{(2^{15}+2^{10})+2(2^{13}+2^{12})+2(2^{11}+2^{14})+2(2^9+2^{16})+2(2^7+2^2)+2(2^5+2^4)+2(2^3+2^6)+2(2^1+2^8)+1} \right) \\
 & + 2^{2^7+2} \left(2^{(2^{15}+2^8)+2(2^{13}+2^6)+2(2^{11}+2^4)+2(2^9+2^2)+2(2^7+2^{14})+2(2^5+2^{16})+2(2^3+2^{10})+2(2^1+2^{12})+1} \right) \\
 & + 2^{2^5+2} \left(2^{(2^{15}+2^6)+2(2^{13}+2^8)+2(2^{11}+2^2)+2(2^9+2^4)+2(2^7+2^{16})+2(2^5+2^{14})+2(2^3+2^{12})+2(2^1+2^{10})+1} \right) \\
 & + 2^{2^3+2} \left(2^{(2^{15}+2^4)+2(2^{13}+2^2)+2(2^{11}+2^8)+2(2^9+2^6)+2(2^7+2^{10})+2(2^5+2^{12})+2(2^3+2^{14})+2(2^1+2^{16})+1} \right) \\
 & + 2^{2^1+2} \left(2^{(2^{15}+2^2)+2(2^{13}+2^4)+2(2^{11}+2^6)+2(2^9+2^8)+2(2^7+2^{12})+2(2^5+2^{10})+2(2^3+2^{16})+2(2^1+2^{14})+1} \right) .
 \end{aligned}$$

Quaternion Group Q_8 . Consider G with six objects of order 4. Let a the only object of second order.

e	a	b	x_1	c	x_2	d	x_3
a	e						
b	x_1	a					
x_1	b		a				
c	x_2			a			
x_2	c				a		
d	x_3					a	
x_3	d						a

Find $x_1 * b = e$ and $b * x_1 = e$, using associativity. It can also be verified that $b * a = b^3 = a * b$. Using associativity it can be found $x_1 * a = b$.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b				
b	x_1	a	e				
x_1	b	e	a				
c	x_2			a			
x_2	c				a		
d	x_3					a	
x_3	d						a

Suppose, without loss of generality, $b * c = d$.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b				
b	x_1	a	e				
x_1	b	e	a				
c	x_2	d	x_3	a			
x_2	c	x_3	d		a		
d	x_3	x_2	c			a	
x_3	d	c	x_2				a

Use associativity, as usual, to find

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b				
b	x_1	a	e				
x_1	b	e	a				
c	x_2	d	x_3	a	e		
x_2	c	x_3	d	e	a		
d	x_3	x_2	c			a	e
x_3	d	c	x_2			e	a

It is true $c * a = c^3 = a * c$; then, use associativity to find $x_2 * a$. In a similar fashion, $d * a = d^3 = a * d$ and $x_3 * a = d$ can be found.

e	a	b	x_1	c	x_2	d	x_3
a	e	x_1	b	x_2	c	x_3	d
b	x_1	a	e				
x_1	b	e	a				
c	x_2	d	x_3	a	e		
x_2	c	x_3	d	e	a		
d	x_3	x_2	c			a	e
x_3	d	c	x_2			e	a

Next use $c = x_1 * d$ to find $c * d = x_1 * (d * d) = x_1 * a = b$. The rest of the table is determined as usual. Written in generic variables $g_1, g_2, g_3, g_4, g_5, g_6, g_7$,

e	g_1	g_2	g_3	g_4	g_5	g_6	g_7
g_1	e	g_3	g_2	g_5	g_4	g_7	g_6
g_2	g_3	g_1	e	g_7	g_6	g_4	g_5
g_3	g_2	e	g_1	g_6	g_7	g_5	g_4
g_4	g_5	g_6	g_7	g_1	e	g_3	g_2
g_5	g_4	g_7	g_6	e	g_1	g_2	g_3
g_6	g_7	g_5	g_4	g_2	g_3	g_1	e
g_7	g_6	g_4	g_5	g_3	g_2	e	g_1

This group was determined by the conditions of having one second order object, g_1 , and $g_1 = g_2^2 = g_3^2 = g_4^2 = g_5^2 = g_6^2$. Thus, the system of equations

$$g_1^2 = e$$

$$g_2^2 = g_4^2 = (g_1 * g_2)^2 = (g_1 * g_4)^2 = (g_2 * g_4)^2 = (g_4 * g_2)^2 = g_1.$$

determines the quaternion group Q_8 . To find the canonical naming functions, start with $e = 7$ and $g_1 = a = 6$ because g_1 is the only second order object. Then, choose a fourth order object to take the numerical value $b = 5$, and $x_1 = a * b = 4$. This object, b , is chosen from six possible objects of fourth order. Then, choose another object $c = 3$, and $a * c = x_2 = 2$,

$b * c = d = 1, a * d = x_3 = 0$. The element c is chosen from four remaining group elements. All the fourth order objects are equivalent and there is a total of twenty four canonical naming functions and automorphisms. The numeric table given by the canonical naming functions is

7	6	5	4	3	2	1	0
6	7	4	5	2	3	0	1
5	4	6	7	0	1	3	2
4	5	7	6	1	0	2	3
3	2	1	0	6	7	4	5
2	3	0	1	7	6	5	4
1	0	2	3	5	4	6	7
0	1	3	2	4	5	7	6

The canonical representation is

$$\begin{aligned}
 N_{Q_8} = & 2^{2^{15}+2} \left(2^{(2^{15}+2^{16})+2(2^{13}+2^{14})+2(2^{11}+2^{12})+2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1} \right) \\
 & + 2^{2^{13}+2} \left(2^{(2^{15}+2^{14})+2(2^{13}+2^{16})+2(2^{11}+2^{10})+2(2^9+2^{12})+2(2^7+2^6)+2(2^5+2^8)+2(2^3+2^2)+2(2^1+2^4)+1} \right) \\
 & + 2^{2^{11}+2} \left(2^{(2^{15}+2^{12})+2(2^{13}+2^{10})+2(2^{11}+2^{14})+2(2^9+2^{16})+2(2^7+2^4)+2(2^5+2^2)+2(2^3+2^6)+2(2^1+2^8)+1} \right) \\
 & + 2^{2^9+2} \left(2^{(2^{15}+2^{10})+2(2^{13}+2^{12})+2(2^{11}+2^{16})+2(2^9+2^{14})+2(2^7+2^2)+2(2^5+2^4)+2(2^3+2^8)+2(2^1+2^6)+1} \right) \\
 & + 2^{2^7+2} \left(2^{(2^{15}+2^8)+2(2^{13}+2^6)+2(2^{11}+2^2)+2(2^9+2^4)+2(2^7+2^{14})+2(2^5+2^{16})+2(2^3+2^{12})+2(2^1+2^{10})+1} \right) \\
 & + 2^{2^5+2} \left(2^{(2^{15}+2^6)+2(2^{13}+2^8)+2(2^{11}+2^4)+2(2^9+2^2)+2(2^7+2^{16})+2(2^5+2^{14})+2(2^3+2^{10})+2(2^1+2^{12})+1} \right) \\
 & + 2^{2^3+2} \left(2^{(2^{15}+2^4)+2(2^{13}+2^2)+2(2^{11}+2^8)+2(2^9+2^6)+2(2^7+2^{10})+2(2^5+2^{12})+2(2^3+2^{14})+2(2^1+2^{16})+1} \right) \\
 & + 2^{2^1+2} \left(2^{(2^{15}+2^2)+2(2^{13}+2^4)+2(2^{11}+2^6)+2(2^9+2^8)+2(2^7+2^{12})+2(2^5+2^{10})+2(2^3+2^{16})+2(2^1+2^{14})+1} \right) .
 \end{aligned}$$

Cyclic Group \mathbb{Z}_8 . Finding the cyclic group is trivial, and it is defined by the equations $a^2 = b, b^2 = c, c^2 = e$. It has numeric table

7	6	5	4	3	2	1	0
6	5	4	3	2	1	0	7
5	4	3	2	1	0	7	6
4	3	2	1	0	7	6	5
3	2	1	0	7	6	5	4
2	1	0	7	6	5	4	3
1	0	7	6	5	4	3	2
0	7	6	5	4	3	2	1

The canonical representation of this group being

$$\begin{aligned}
N_{\mathbb{Z}_8} = & 2^{2^{15}+2} \left(2^{(2^{15}+2^{16})+2(2^{13}+2^{14})+2(2^{11}+2^{12})+2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1} \right) \\
& + 2^{2^{13}+2} \left(2^{(2^{15}+2^{14})+2(2^{13}+2^{12})+2(2^{11}+2^{10})+2(2^9+2^8)+2(2^7+2^6)+2(2^5+2^4)+2(2^3+2^2)+2(2^1+2^{16})+1} \right) \\
& + 2^{2^{11}+2} \left(2^{(2^{15}+2^{12})+2(2^{13}+2^{10})+2(2^{11}+2^8)+2(2^9+2^6)+2(2^7+2^4)+2(2^5+2^2)+2(2^3+2^{16})+2(2^1+2^{14})+1} \right) \\
& + 2^{2^9+2} \left(2^{(2^{15}+2^{10})+2(2^{13}+2^8)+2(2^{11}+2^6)+2(2^9+2^4)+2(2^7+2^2)+2(2^5+2^{16})+2(2^3+2^{14})+2(2^1+2^{12})+1} \right) \\
& + 2^{2^7+2} \left(2^{(2^{15}+2^8)+2(2^{13}+2^6)+2(2^{11}+2^4)+2(2^9+2^2)+2(2^7+2^{16})+2(2^5+2^{14})+2(2^3+2^{12})+2(2^1+2^{10})+1} \right) \\
& + 2^{2^5+2} \left(2^{(2^{15}+2^6)+2(2^{13}+2^4)+2(2^{11}+2^2)+2(2^9+2^{16})+2(2^7+2^{14})+2(2^5+2^{12})+2(2^3+2^{10})+2(2^1+2^8)+1} \right) \\
& + 2^{2^3+2} \left(2^{(2^{15}+2^4)+2(2^{13}+2^2)+2(2^{11}+2^{16})+2(2^9+2^{14})+2(2^7+2^{12})+2(2^5+2^{10})+2(2^3+2^8)+2(2^1+2^6)+1} \right) \\
& + 2^{2^1+2} \left(2^{(2^{15}+2^2)+2(2^{13}+2^{16})+2(2^{11}+2^{14})+2(2^9+2^{12})+2(2^7+2^{10})+2(2^5+2^8)+2(2^3+2^6)+2(2^1+2^4)+1} \right).
\end{aligned}$$

Groups of eight elements have been ordered; $\mathbb{Z}_8 < Q_8 < D_8 < \mathbb{Z}_2 \oplus \mathbb{Z}_4 < \mathbb{Z}_2^3$.

Appendix 4 $|G| = 9$

Direct Product $\mathbb{Z}_3 \oplus \mathbb{Z}_3$. If $|G| = 9$ then $|g| = 3$ or $|g| = 9$ for any $g \in G$. Start by searching for groups with all objects of order 3. The function $*x_1$ is equal to the composition $*a \circ *a$. Since $|b| = 3$, it is true $b^2 \neq a$. If $b^2 = a$, then $b * a = e$ which is a contradiction. Suppose $b^2 = c$, without loss of generality.

e	a	x_1	b	x_2	x_3	c	x_4	x_5
a	x_1	e						
x_1	e	a						
b	x_2	x_3	c					
x_2	x_3	b						
x_3	b	x_2						
c	x_4	x_5	e					
x_4	x_5	c						
x_5	c	x_4						

The rest of the rows of b and c are found using associativity.

e	a	x_1	b	x_2	x_3	c	x_4	x_5
a	x_1	e						
x_1	e	a						
b	x_2	x_3	c	x_4	x_5	e	a	x_1
x_2	x_3	b						
x_3	b	x_2						
c	x_4	x_5	e	a	x_1	b	x_2	x_3
x_4	x_5	c						
x_5	c	x_4						

Check for a non abelian group. The first option for this is $b * a = x_3$, which implies $x_2 * a = b$. There is a contradiction because $|x_2| = 3$ implies $x_2 * x_4 = a$. There is also a contradiction if $b * a = x_4$. This relation implies $x_3 * a = c$. The last expression together with $|x_3| = 3$ implies $x_3 * x_1 = a$, which is a contradiction with $x_1^2 = a$. The supposition $b * a = x_5$ implies $x_2 * a = c$. This, together with $x_2 * c = a$ is a contradiction with the

fact that $|x_2| = 3$. It can be concluded $b * a = x_2$. Then it can be found $x_2 * a = x_3$ and $x_3 * a = b$. Use the last expression to find $b * x_1 = x_3$.

e	a	x_1	b	x_2	x_3	c	x_4	x_5
a	x_1	e	x_2	x_3	b			
x_1	e	a	x_3	b	x_2			
b	x_2	x_3	c	x_4	x_5	e	a	x_1
x_2	x_3	b						
x_3	b	x_2						
c	x_4	x_5	e	a	x_1	b	x_2	x_3
x_4	x_5	c						
x_5	c	x_4						

Use the expression $b = x_2 * x_1$ to find $b * x_2 = x_4$. Then use $b = x_2 * x_1$ to find $b * x_4 = a$.

e	a	x_1	b	x_2	x_3	c	x_4	x_5
a	x_1	e	x_2	x_3	b			
x_1	e	a	x_3	b	x_2			
b	x_2	x_3	c	x_4	x_5	e	a	x_1
x_2	x_3	b	x_4	x_5	c			
x_3	b	x_2	x_5	c	x_4			
c	x_4	x_5	e	a	x_1	b	x_2	x_3
x_4	x_5	c	a	x_1	e			
x_5	c	x_4	x_1	e	a			

Finding the rest of the table is trivial. The result is the direct product group $\mathbb{Z}_3 \oplus \mathbb{Z}_3$. The system of equations that defines this group is given by the relations

$$\begin{aligned} a^2 &= x_1 \\ b^2 &= c \\ a^3 = b^3 &= e \\ a * b &= b * a. \end{aligned}$$

This group is determined by two commuting third order elements such that neither is the square of the other. To find the canonical naming function of this group begin by expressing the table in generic variables g_i .

e	g_1	g_2	g_3	g_4	g_5	g_6	g_7	g_8
g_1	g_2	e	g_4	g_5	g_3	g_7	g_8	g_6
g_2	e	g_1	g_5	g_3	g_4	g_8	g_6	g_7
g_3	g_4	g_5	g_6	g_7	g_8	e	g_1	g_2
g_4	g_5	g_3	g_7	g_8	g_6	g_1	g_2	e
g_5	g_3	g_4	g_8	g_6	g_7	g_2	e	g_1
g_6	g_7	g_8	e	g_1	g_2	g_3	g_4	g_5
g_7	g_8	g_6	g_1	g_2	e	g_4	g_5	g_3
g_8	g_6	g_7	g_2	e	g_1	g_5	g_3	g_4

Observe that the group is commutative. The group naming will be determined by choosing any two objects a, b that satisfy the conditions mentioned above. Let $e = 8$ and choose an arbitrary $a = 7$. Then $a^2 = 6$ maximizes the representation. The object a is chosen from eight possible choices. Next choose a second object $b = 5$, and assign the name $a * b = x_2 = 4$ and $a * x_2 = 3$. This object b can be chosen from six remaining objects. Finally, assign the values $b^2 = c = 2$, $a * c = x_4 = 1$, $a * x_4 = x_5 = 0$. This has determined a

total of forty eight canonical naming functions and automorphisms of \mathbb{Z}_3^2 . Choosing the two objects a, b determines the rest of the naming values. This gives the numeric table

8	7	6	5	4	3	2	1	0
7	6	8	4	3	5	1	0	2
6	8	7	3	5	4	0	2	1
5	4	3	2	1	0	8	7	6
4	3	5	1	0	2	7	6	8
3	5	4	0	2	1	6	8	7
2	1	0	8	7	6	5	4	3
1	0	2	7	6	8	4	3	5
0	2	1	6	8	7	3	5	4

The canonical representation of this group is the number

$$\begin{aligned}
 N_{\mathbb{Z}_3^2} = & 2^{2^{17}+2} \left(2^{(2^{17}+2^{18})+2(2^{15}+2^{16})+2(2^{13}+2^{14})+2(2^{11}+2^{12})+2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1} \right) \\
 & + 2^{2^{15}+2} \left(2^{(2^{17}+2^{16})+2(2^{15}+2^{14})+2(2^{13}+2^{18})+2(2^{11}+2^{10})+2(2^9+2^8)+2(2^7+2^{12})+2(2^5+2^4)+2(2^3+2^2)+2(2^1+2^6)+1} \right) \\
 & + 2^{2^{13}+2} \left(2^{(2^{17}+2^{14})+2(2^{15}+2^{18})+2(2^{13}+2^{16})+2(2^{11}+2^8)+2(2^9+2^{12})+2(2^7+2^{10})+2(2^5+2^2)+2(2^3+2^6)+2(2^1+2^4)+1} \right) \\
 & + 2^{2^{11}+2} \left(2^{(2^{17}+2^{12})+2(2^{15}+2^{10})+2(2^{13}+2^8)+2(2^{11}+2^6)+2(2^9+2^4)+2(2^7+2^2)+2(2^5+2^{18})+2(2^3+2^{16})+2(2^1+2^{14})+1} \right) \\
 & + 2^{2^9+2} \left(2^{(2^{17}+2^{10})+2(2^{15}+2^8)+2(2^{13}+2^{12})+2(2^{11}+2^4)+2(2^9+2^2)+2(2^7+2^6)+2(2^5+2^{16})+2(2^3+2^{14})+2(2^1+2^{18})+1} \right) \\
 & + 2^{2^7+2} \left(2^{(2^{17}+2^8)+2(2^{15}+2^{12})+2(2^{13}+2^{10})+2(2^{11}+2^2)+2(2^9+2^6)+2(2^7+2^4)+2(2^5+2^{14})+2(2^3+2^{18})+2(2^1+2^{16})+1} \right) \\
 & + 2^{2^5+2} \left(2^{(2^{17}+2^6)+2(2^{15}+2^4)+2(2^{13}+2^2)+2(2^{11}+2^{18})+2(2^9+2^{16})+2(2^7+2^{14})+2(2^5+2^{12})+2(2^3+2^{10})+2(2^1+2^8)+1} \right) \\
 & + 2^{2^3+2} \left(2^{(2^{17}+2^4)+2(2^{15}+2^2)+2(2^{13}+2^6)+2(2^{11}+2^{16})+2(2^9+2^{14})+2(2^7+2^{18})+2(2^5+2^{10})+2(2^3+2^8)+2(2^1+2^{12})+1} \right) \\
 & + 2^{2^1+2} \left(2^{(2^{17}+2^2)+2(2^{15}+2^6)+2(2^{13}+2^4)+2(2^{11}+2^{14})+2(2^9+2^{18})+2(2^7+2^{16})+2(2^5+2^8)+2(2^3+2^{12})+2(2^1+2^{10})+1} \right) .
 \end{aligned}$$

Cyclic Group \mathbb{Z}_9 . If $|G| = 9$, the objects of G have order 3 or 9. The only group with all objects of order three has been found. Now consider the case where there exists at least one object of order 9. But, since the group has nine objects, this must be the cyclic group, \mathbb{Z}_9 . The cyclic group of nine objects is trivially given by the numeric table

8	7	6	5	4	3	2	1	0
7	6	5	4	3	2	1	0	8
6	5	4	3	2	1	0	8	7
5	4	3	2	1	0	8	7	6
4	3	2	1	0	8	7	6	5
3	2	1	0	8	7	6	5	4
2	1	0	8	7	6	5	4	3
1	0	8	7	6	5	4	3	2
0	8	7	6	5	4	3	2	1

The canonical representation is

$$\begin{aligned}
N_{\mathbb{Z}_9} = & 2^{2^{17}+2} \left(2^{2^{(2^{17}+2^{18})+2(2^{15}+2^{16})+2(2^{13}+2^{14})+2(2^{11}+2^{12})+2(2^9+2^{10})+2(2^7+2^8)+2(2^5+2^6)+2(2^3+2^4)+2(2^1+2^2)+1}} \right) \\
& + 2^{2^{15}+2} \left(2^{2^{(2^{17}+2^{16})+2(2^{15}+2^{14})+2(2^{13}+2^{12})+2(2^{11}+2^{10})+2(2^9+2^8)+2(2^7+2^6)+2(2^5+2^4)+2(2^3+2^2)+2(2^1+2^{18})+1}} \right) \\
& + 2^{2^{13}+2} \left(2^{2^{(2^{17}+2^{14})+2(2^{15}+2^{12})+2(2^{13}+2^{10})+2(2^{11}+2^8)+2(2^9+2^6)+2(2^7+2^4)+2(2^5+2^2)+2(2^3+2^{18})+2(2^1+2^{16})+1}} \right) \\
& + 2^{2^{11}+2} \left(2^{2^{(2^{17}+2^{12})+2(2^{15}+2^{10})+2(2^{13}+2^8)+2(2^{11}+2^6)+2(2^9+2^4)+2(2^7+2^2)+2(2^5+2^{18})+2(2^3+2^{16})+2(2^1+2^{14})+1}} \right) \\
& + 2^{2^9+2} \left(2^{2^{(2^{17}+2^{10})+2(2^{15}+2^8)+2(2^{13}+2^6)+2(2^{11}+2^4)+2(2^9+2^2)+2(2^7+2^{18})+2(2^5+2^{16})+2(2^3+2^{14})+2(2^1+2^{12})+1}} \right) \\
& + 2^{2^7+2} \left(2^{2^{(2^{17}+2^8)+2(2^{15}+2^6)+2(2^{13}+2^4)+2(2^{11}+2^2)+2(2^9+2^{18})+2(2^7+2^{16})+2(2^5+2^{14})+2(2^3+2^{12})+2(2^1+2^{10})+1}} \right) \\
& + 2^{2^5+2} \left(2^{2^{(2^{17}+2^6)+2(2^{15}+2^4)+2(2^{13}+2^2)+2(2^{11}+2^{18})+2(2^9+2^{16})+2(2^7+2^{14})+2(2^5+2^{12})+2(2^3+2^{10})+2(2^1+2^8)+1}} \right) \\
& + 2^{2^3+2} \left(2^{2^{(2^{17}+2^4)+2(2^{15}+2^2)+2(2^{13}+2^{18})+2(2^{11}+2^{16})+2(2^9+2^{14})+2(2^7+2^{12})+2(2^5+2^{10})+2(2^3+2^8)+2(2^1+2^6)+1}} \right) \\
& + 2^{2^1+2} \left(2^{2^{(2^{17}+2^2)+2(2^{15}+2^{18})+2(2^{13}+2^{16})+2(2^{11}+2^{14})+2(2^9+2^{12})+2(2^7+2^{10})+2(2^5+2^8)+2(2^3+2^6)+2(2^1+2^4)+1}} \right) .
\end{aligned}$$

Comparing the two numbers, it is verified $\mathbb{Z}_9 < \mathbb{Z}_3^2$. It is becoming more clear how to find the canonical representation, without having to calculate all the representations. But there are still several considerations before attacking the general case.

The canonical block form of the symmetric group Δ_4 is calculated, as another example.

Appendix .5 Δ_4

The multiplication table of Δ_4 is exhibited for reference. The symbols g_i are used for the elements of order 2, and h_i for the rest of the objects.

e	g_1	g_2	g_3	g_4	g_5	g_6	g_7	g_8	g_9	h_1	h_2	h_3	h_4	h_5	h_6	h_7	h_8	h_9	h_{10}	h_{11}	h_{12}	h_{13}	h_{14}
g_1	e	g_4	g_5	g_2	g_3	h_2	h_1	h_4	h_3	g_7	g_6	g_9	g_8	h_6	h_5	h_{12}	h_{11}	h_{14}	h_{13}	h_8	h_7	h_{10}	h_9
g_2	g_4	e	h_6	g_1	h_5	h_1	h_2	g_9	g_8	g_6	g_7	h_4	h_3	g_5	g_3	h_{11}	h_{12}	h_{10}	h_9	h_7	h_8	h_{14}	h_{13}

(A6)

It is noted, ahead of time, the canonical naming function does not assign the ten highest values to the set $\{e, g_1, g_2, \dots, g_9\}$. Some h_i objects will have a higher numeric value than some g_i . The smallest order of any non trivial object is 2. It is obvious $e = 23, 23 = a, 22 = b$ for two second order objects, a, b , that commute. The possible pairs are:

$$\begin{array}{ll}
 \{g_1, g_2\} & \{g_4, g_6\} \\
 \{g_1, g_4\} & \{g_4, g_7\} \\
 \{g_2, g_4\} & \{g_6, g_7\} \\
 \{g_1, g_3\} & \{g_2, g_8\} \\
 \{g_1, g_5\} & \{g_2, g_9\} \\
 \{g_3, g_5\} & \{g_8, g_9\}
 \end{array} \quad (A7)$$

Let a, b any of these pairs; the pairs can be used in either order because they are not ordered pairs. For example, a naming can be $a = g_1, b = g_2$, or $a = g_2, b = g_1$. Any of the pairs above determine the naming function $e = 23, a = 22, b = 21, x_1 = 20$ with table

$$\begin{array}{cccc}
 e & a & b & x_1 \\
 a & e & x_1 & b \\
 b & x_1 & e & a \\
 x_1 & b & a & e
 \end{array}$$

To maximize the representation, find a, b, x_1 such that $\{e, a, b, x_1\}$ forms the Klein 4-group. In fact, the triads

$$\{g_1, g_2, g_4\} \quad \{g_1, g_3, g_5\} \quad \{g_4, g_6, g_7\} \quad \{g_2, g_8, g_9\} \quad (A8)$$

form the Klein 4-group. Given any one of these triads, it is unknown which objects will be a and b . For example, using $\{g_1, g_2, g_4\}$, who should we define as a, b, x_1 ? All the non trivial objects of $K(4)$ are equivalent, so this can not be decided yet.

Add a new object c_1 and $x_2 = a * c_1$.

e	a	b	x_1	c_1	x_2
a	e	x_1	b		
b	x_1	e	a		
x_1	b	a	e		
c_1	x_2				
x_2	c_1				

Another new object is needed also, $c_2 = b * c_1$, then $x_3 = a * c_2$.

e	a	b	x_1	c_1	x_2	c_2	x_3
a	e	x_1	b				
b	x_1	e	a				
x_1	b	a	e				
c_1	x_2	c_2	x_3				
x_2	c_1	x_3	c_2				
c_2	x_3	c_1	x_2				
x_3	c_2	x_2	c_1				

In summary, the canonical naming function will involve one of the Klein 4-subgroups $\{e, a, b, x_1\}$ of Δ_4 , and an object c_1 that commutes with a , if it should exist. This maximizes the table. There are several options to do this. In fact, all the candidate naming functions admit an object c_1 that commutes with a . This gives the table

e	a	b	x_1	c_1	x_2	c_2	x_3
a	e	x_1	b	x_2	c_1		
b	x_1	e	a				
x_1	b	a	e				
c_1	x_2	c_2	x_3				
x_2	c_1	x_3	c_2				
c_2	x_3	c_1	x_2				
x_3	c_2	x_2	c_1				

determined by the equations

$$\begin{aligned} e &= a^2 = b^2 \\ a * b &= b * a \\ a * c_1 &= c_1 * a. \end{aligned}$$

For the triads in (A8), it is necessary to find an object c_1 that commutes with a . For example, all the objects in $\{g_1, g_2, g_4\}$ commute with at least one object not in that set. In the case of $\{g_2, g_8, g_9\}$, only g_2 commutes with objects not in that list. This means if the triad $\{g_2, g_8, g_9\}$ is chosen, then $a = g_2$. For $\{g_1, g_3, g_5\}$ it must be true $a = g_1$, and for $\{g_4, g_6, g_7\}$ the naming $a = g_4$ must be given. The objects that commute with each second order object g_i are listed.

$$\begin{aligned} \text{Comm}(g_1) &= \{g_2, g_4, g_3, g_5, h_5, h_6\} & \text{Comm}(g_2) &= \{g_1, g_4, g_8, g_9, h_3, h_4\} & \text{Comm}(g_3) &= \{g_1, g_5\} \\ \text{Comm}(g_4) &= \{g_1, g_2, g_6, g_7, h_1, h_2\} & \text{Comm}(g_5) &= \{g_1, g_3\} & \text{Comm}(g_6) &= \{g_4, g_7\} \\ \text{Comm}(g_7) &= \{g_4, g_6\} & \text{Comm}(g_8) &= \{g_2, g_9\} & \text{Comm}(g_9) &= \{g_2, g_8\} \end{aligned} \quad (\text{A9})$$

This information reduces the possible naming functions because a little more is known about a . The possible naming functions are more than would be practical to list, but

they are easy to describe. An object $a \in \{g_1, g_2, g_4\}$ is needed, along with a second order object b that together determine the subgroup $K(4)$. For example, if $a = g_4$, then one can choose $b \in \{g_1, g_2, g_6, g_7\}$; find a second order object that commutes with $a = g_4$. In the case of $a = g_1$, one must choose $b \in \{g_2, g_4, g_3, g_5\}$. If $a = g_2$ then $b \in \{g_1, g_4, g_8, g_9\}$. After determining the subgroup $K(4)$, an object c_1 that commutes with a is needed. The expressions of (A9) determine which combinations allow c_1 . Start representing naming functions with finite sequences; in the form $(a, b, x_1, c_1, x_2, c_2, x_3)$. For example, the naming function $a = g_4, b = g_2, x_1 = a * b = g_1, c_1 = g_7, x_2 = a * c_1 = g_6, c_2 = b * c_1 = h_1, x_3 = a * c_2 = h_2$ is given by the expression $(g_4, g_2, g_1, g_7, g_6, h_1, h_2)$. It is already known $a \in g_1, g_2, g_4$ for any of the triads giving $K(4)$. Choose a second order object, b , that commutes with a , and then choose an object c_1 that also commutes with a . All possible naming functions are listed below.

$$\begin{array}{lll}
 (g_1, g_2, g_4, g_3, g_5, h_5, h_6) & (g_2, g_1, g_4, g_8, g_9, h_3, h_4) & (g_4, g_1, g_2, g_6, g_7, h_1, h_2) \\
 (g_1, g_2, g_4, g_5, g_3, h_6, h_5) & (g_2, g_1, g_4, g_9, g_8, h_4, h_3) & (g_4, g_1, g_2, g_7, g_6, h_2, h_1) \\
 (g_1, g_2, g_4, h_5, h_6, g_3, g_5) & (g_2, g_1, g_4, h_3, h_4, g_8, g_9) & (g_4, g_1, g_2, h_1, h_2, g_6, g_7) \\
 (g_1, g_2, g_4, h_6, h_5, g_5, g_3) & (g_2, g_1, g_4, h_4, h_3, g_9, g_8) & (g_4, g_1, g_2, h_2, h_1, g_7, g_6) \\
 \\
 (g_1, g_4, g_2, g_3, g_5, h_6, h_5) & (g_2, g_4, g_1, g_8, g_9, h_4, h_3) & (g_4, g_2, g_1, g_6, g_7, h_2, h_1) \\
 (g_1, g_4, g_2, g_5, g_3, h_5, h_6) & (g_2, g_4, g_1, g_9, g_8, h_3, h_4) & (g_4, g_2, g_1, g_7, g_6, h_1, h_2) \\
 (g_1, g_4, g_2, h_5, h_6, g_5, g_3) & (g_2, g_4, g_1, h_3, h_4, g_9, g_8) & (g_4, g_2, g_1, h_1, h_2, g_7, g_6) \\
 (g_1, g_4, g_2, h_6, h_5, g_3, g_5) & (g_2, g_4, g_1, h_4, h_3, g_8, g_9) & (g_4, g_2, g_1, h_2, h_1, g_6, g_7) \\
 \\
 (g_1, g_3, g_5, g_2, g_4, h_6, h_5) & (g_2, g_8, g_9, g_1, g_4, h_4, h_3) & (g_4, g_6, g_7, g_1, g_2, h_2, h_1) \\
 (g_1, g_3, g_5, g_4, g_2, h_5, h_6) & (g_2, g_8, g_9, g_4, g_1, h_3, h_4) & (g_4, g_6, g_7, g_2, g_1, h_1, h_2) \\
 (g_1, g_3, g_5, h_5, h_6, g_4, g_2) & (g_2, g_8, g_9, h_3, h_4, g_4, g_1) & (g_4, g_6, g_7, h_1, h_2, g_2, g_1) \\
 (g_1, g_3, g_5, h_6, h_5, g_2, g_4) & (g_2, g_8, g_9, h_4, h_3, g_1, g_4) & (g_4, g_6, g_7, h_2, h_1, g_1, g_2) \\
 \\
 (g_1, g_5, g_3, g_2, g_4, h_5, h_6) & (g_2, g_9, g_8, g_1, g_4, h_3, h_4) & (g_4, g_7, g_6, g_1, g_2, h_1, h_2) \\
 (g_1, g_5, g_3, g_4, g_2, h_6, h_5) & (g_2, g_9, g_8, g_4, g_1, h_4, h_3) & (g_4, g_7, g_6, g_2, g_1, h_2, h_1) \\
 (g_1, g_5, g_3, h_5, h_6, g_2, g_4) & (g_2, g_9, g_8, h_3, h_4, g_1, g_4) & (g_4, g_7, g_6, h_1, h_2, g_1, g_2) \\
 (g_1, g_5, g_3, h_6, h_5, g_4, g_2) & (g_2, g_9, g_8, h_4, h_3, g_4, g_1) & (g_4, g_7, g_6, h_2, h_1, g_2, g_1)
 \end{array} \tag{A10}$$

In (A9) it can also be observed that given any choice of $K(4) = \{e, a, b, x_1\}$, there is no group element $g \notin K(4)$ that commutes with both a and b . That is to say, $x_1 = a * b$ is the only element of Δ_4 that commutes with a and b . None of the candidate triads satisfy $a * c_1 = c_1 * a$ and $b * c_1 = c_1 * b$ simultaneously. The highest valued object that can be in the position of $c_1 * b$, is x_3 . Each of the finite sequences above satisfies $a * c_1 = c_1 * a$ and $x_3 = c_1 * b$. Any one of the naming functions in (A10) will give the table

e	a	b	x_1	c_1	x_2	c_2	x_3
a	e	x_1	b	x_2	c_1		
b	x_1	e	a	x_3	c_2		
x_1	b	a	e	c_2	x_3		
c_1	x_2	c_2	x_3				
x_2	c_1	x_3	c_2				
c_2	x_3	c_1	x_2				
x_3	c_2	x_2	c_1				

It is possible to choose c_1 with the additional restraint $|c_1| = 2$, maximizing the representation. The naming functions

$$\begin{array}{lll}
 (g_1, g_2, g_4, g_3, g_5, h_5, h_6) & (g_2, g_1, g_4, g_8, g_9, h_3, h_4) & (g_4, g_1, g_2, g_6, g_7, h_1, h_2) \\
 (g_1, g_2, g_4, g_5, g_3, h_6, h_5) & (g_2, g_1, g_4, g_9, g_8, h_4, h_3) & (g_4, g_1, g_2, g_7, g_6, h_2, h_1) \\
 \\
 (g_1, g_4, g_2, g_3, g_5, h_6, h_5) & (g_2, g_4, g_1, g_8, g_9, h_4, h_3) & (g_4, g_2, g_1, g_6, g_7, h_2, h_1) \\
 (g_1, g_4, g_2, g_5, g_3, h_5, h_6) & (g_2, g_4, g_1, g_9, g_8, h_3, h_4) & (g_4, g_2, g_1, g_7, g_6, h_1, h_2) \\
 \\
 (g_1, g_3, g_5, g_2, g_4, h_6, h_5) & (g_2, g_8, g_9, g_1, g_4, h_4, h_3) & (g_4, g_6, g_7, g_1, g_2, h_2, h_1) \\
 (g_1, g_3, g_5, g_4, g_2, h_5, h_6) & (g_2, g_8, g_9, g_4, g_1, h_3, h_4) & (g_4, g_6, g_7, g_2, g_1, h_1, h_2) \\
 \\
 (g_1, g_5, g_3, g_2, g_4, h_5, h_6) & (g_2, g_9, g_8, g_1, g_4, h_3, h_4) & (g_4, g_7, g_6, g_1, g_4, h_1, h_2) \\
 (g_1, g_5, g_3, g_4, g_2, h_6, h_5) & (g_2, g_9, g_8, g_4, g_1, h_4, h_3) & (g_4, g_7, g_6, g_2, g_1, h_2, h_1)
 \end{array} \tag{A11}$$

give the Dihedral Group

e	a	b	x_1	c_1	x_2	c_2	x_3
a	e	x_1	b	x_2	c_1	x_3	c_2
b	x_1	e	a	x_3	c_2	x_2	c_1
x_1	b	a	e	c_2	x_3	c_1	x_2
c_1	x_2	c_2	x_3	e	a	b	x_1
x_2	c_1	x_3	c_2	a	e	x_1	b
c_2	x_3	c_1	x_2	x_1	b	a	e
x_3	c_2	x_2	c_1	b	x_1	e	a

Add a new object d_1 to the table above. The operation $b * d_1$ is a new object, d_2 . The operation $c_1 * d_1$ is also a new object, p_1 . Finally, $p_2 = b * p_1$ to maximize the representation.

e	a	b	x_1	c_1	x_2	c_2	x_3	d_1	x_4	d_2	x_5	p_1	x_6	p_2	x_7
a	e	x_1	b	x_2	c_1	x_3	c_2								
b	x_1	e	a	x_3	c_2	x_2	c_1								
x_1	b	a	e	c_2	x_3	c_1	x_2								
c_1	x_2	c_2	x_3	e	a	b	x_1								
x_2	c_1	x_3	c_2	a	e	x_1	b								
c_2	x_3	c_1	x_2	x_1	b	a	e								
x_3	c_2	x_2	c_1	b	x_1	e	a								
d_1	x_4	d_2	x_5	p_1	x_6	p_2	x_7								
x_4	d_1	x_5	d_2	x_6	p_1	x_7	p_2								
d_2	x_5	d_1	x_4	x_7	p_2	x_6	p_1								
x_5	d_2	x_4	d_1	p_2	x_7	p_1	x_6								
p_1	x_6	p_2	x_7	d_1	x_4	d_2	x_5								
x_6	p_1	x_7	p_2	x_4	d_1	x_5	d_2								
p_2	x_7	p_1	x_6	x_5	d_2	x_4	d_1								
x_7	p_2	x_6	p_1	d_2	x_5	d_1	x_4								

How is d_1 chosen? If there is another object(s) that commutes with a , it would be candidate to d_1 . However, in each of the naming functions, there are no more objects that commute with a . The next largest value that can be placed in $d_1 * a$, is $d_2 = b * d_1$. Observe that only some of the naming functions above will satisfy this condition. For example, the naming function $a = g_1, b = g_3$ is disqualified from being a canonical naming function because there is no element $d_1 \notin D_8$ such that $d_1 * a = b * d_1$. The only cases when such an object d_1 exists is if $a, b \in \{g_1, g_2, g_4\}$. The easiest way to find the candidates for d_1 , is to compare the row of a and the column of b . If the i -th object in the row of a coincides with the i -th object in the column of b , then the i -th object on the first row (or first column)

is a candidate for d_1 . For example, with the naming function $(g_1, g_2, g_4, g_3, g_5, h_5, h_6)$, the candidates for d_1 are the objects $g_6, g_7, h_1, h_2, h_9, h_{10}, h_{13}, h_{14}$. The candidates for d_1 are determined by a, b . If $a = g_1$ and $b = g_3$ there is no candidate for d_1 . If $a = g_1$ and $b = g_4$ the candidates for d_1 are $g_8, g_9, h_3, h_4, h_7, h_8, h_{11}, h_{12}$, etc. The naming functions that satisfy this condition are those that have a, b in g_1, g_2, g_4 . More is known about the canonical naming function. The Klein group $K(4) = \{e, g_1, g_2, g_4\}$, in any order, gives the first four objects of the naming function. Then, a second order object c_1 that commutes with a must be chosen. Then choose d_1 so that $b * d_1 = d_1 * a$. Below, twelve naming functions are given. Each of these has eight possible candidates for d_1 . There is a total of ninety-six possible naming functions.

$$\begin{array}{lll}
 (g_1, g_2, g_4, g_3, g_5, h_5, h_6, d_1, \dots, x_7) & (g_2, g_1, g_4, g_8, g_9, h_3, h_4, d_1, \dots, x_7) & (g_4, g_1, g_2, g_6, g_7, h_1, h_2, d_1, \dots, x_7) \\
 (g_1, g_2, g_4, g_5, g_3, h_6, h_5, d_1, \dots, x_7) & (g_2, g_1, g_4, g_9, g_8, h_4, h_3, d_1, \dots, x_7) & (g_4, g_1, g_2, g_7, g_6, h_2, h_1, d_1, \dots, x_7) \\
 (g_1, g_4, g_2, g_3, g_5, h_6, h_5, d_1, \dots, x_7) & (g_2, g_4, g_1, g_8, g_9, h_4, h_3, d_1, \dots, x_7) & (g_4, g_2, g_1, g_6, g_7, h_2, h_1, d_1, \dots, x_7) \\
 (g_1, g_4, g_2, g_5, g_3, h_5, h_6, d_1, \dots, x_7) & (g_2, g_4, g_1, g_9, g_8, h_3, h_4, d_1, \dots, x_7) & (g_4, g_2, g_1, g_7, g_6, h_1, h_2, d_1, \dots, x_7)
 \end{array} \quad (A12)$$

It is possible to reduce the naming functions, further. Some of the candidate naming functions (not all) satisfy $d_1 * b = a * d_1$, which maximizes the representation. Keep the naming functions that satisfy $b * d_1 = d_1 * a$ and $d_1 * b = a * d_1$, simultaneously. In the case of $a = g_1, b = g_2$ the candidates for d_1 are reduced to g_6, g_7, h_1, h_2 .

e	a	b	x_1	c_1	x_2	c_2	x_3	d_1	x_4	d_2	x_5	p_1	x_6	p_2	x_7

\end{aligned}$$

(A13)

One can start to suspect what objects might turn out to be equivalent. For example, it is quite clear g_1, g_2, g_4 might probably be equivalent, and also g_3, g_5 , and g_6, g_7 , and h_1, h_2 , etc. The naming functions of (A13) all give a new object $d_1 * c_1$. For example, in the naming function $(g_1, g_2, g_4, g_3, g_5, h_5, h_6, g_6, h_1, h_2, g_7)$, there is a new object $d_1 * c_1 = g_6 * g_3 = h_{10}$. Including this new object, $q_1 = d_1 * c_1$, gives another new object $r_1 = c_1 * q_1$. The object $r_1 = c_1 * q_1$ must be added, along with $x_{10} = a * r_1$, $r_2 = b * r_1$, $x_{11} = a * r_2$.

At this point, No more information can be added to the table. An observation is made to complete the table. All the naming functions satisfy $d_1 * p_1 = r_1$. With this, the table is finished.

The canonical naming functions of the symmetry group Δ_4 have been found, and these represent the twenty four automorphisms of Δ_4 . Equivalent objects of the group can be identified. The equivalence classes of objects are

$$\begin{aligned}
 &\{e\} \\
 &\{g_1, g_2, g_4\} \\
 &\{g_3, g_5, g_6, g_7, g_8, g_9\} \\
 &\{h_1, h_2, h_3, h_4, h_5, h_6\} \\
 &\{h_7, h_8, h_9, h_{10}, h_{11}, h_{12}, h_{13}, h_{14}\}
 \end{aligned}$$

The canonical representation is easily obtained from this table in numeric form. To verify isomorphism of two groups, find the numeric tables and these have to coincide.
