Thanks to the pioneering studies of Østerud and co-workers it is now increasingly understood that natural polyphenols present in marine oils play an essential role in protecting omega-3 lipids from oxidation and autooxidation ensuring that no proinflammatory products are formed after intake as it often happens with assumption of refined omega-3 concentrates. Strong antioxidants exerting multiple biological functions, olive biophenols are ideally suited to functionalize marine oils creating a synergy which has the potential to foster public health across the world. This study identifies suitable avenues to advance the sustainable production of health-beneficial formulations based on newly obtained natural marine oils and olive phenolic extracts. Important educational outcomes for bioeconomy educators conclude the study.

1 Introduction

The numerous health benefits of the biophenols found in *Olea europea* include antiatherogenic, cardioprotective, anticancer, and neuroprotective activity [1]. Research in the field is flourishing with book chapters [2] and review articles [3] regularly summarizing newly discovered findings concerning the physiological role of these phenolic compounds, which include oleuropein, hydroxytyrosol, tyrosol and oleocanthal.

Being powerful antioxidants (free radical scavengers [4]), olive phenolic extracts can be used as highly effective non-toxic replacement for toxic, synthetic antioxidants used as preservative food additives [5]. These compounds show also significant anti-inflammatory activity. In the case of hydroxytyrosol (3,4-dihydroxyphenylethanol, HT) quantum mechanical calculations and molecular docking simulations suggest that the anti-inflammatory activity may be due to binding and inhibition of the lipoxygenase and cyclooxygenase enzymes [6].

Another key advantage of relevance in sight of pharmaceutical applications of these phenolics is their lack of toxicity. For example, HT is not genotoxic or mutagenic and its consumption is safe even at high doses [7].

Several olive phenolic extracts have been commercialized as nutraceutical formulations with multiple health benefits [3], ranging from prevention of cardiovascular disease to bone reinforcement, with the use of said formulations being at times supported by clinical evidence from randomized control trials [8].

Similarly, docosahexaenoic acid (DHA, C22:6n-3) and eicosapentaenoic acid (EPA, C20:5n-3) omega-3 (or n-3) long chain polyunsaturated fatty acids (PUFA) abundant in oily blue fish rich exhibit anti-inflammatory, neuroprotective and antithrombotic properties lowering heart rate and blood pressure [9], making consumption of fish and of blue fish in particular of fundamental relevance for physical and mental health of adults and children.

A new index (EPA+DHA in red blood cells) directly related to changes in EPA+DHA intake was introduced by Harris [10] in response to the main deficiency in diets common to industrially
developed countries, namely the insufficient consumption of EPA and DHA.

Increasing the amount of EPA+DHA essential fatty acids in the body requires to either increase consumption of blue fish and seafood, or omega-3 supplementation. Growing at over 10% (compound) annual rate, the $2.6$ EPA/DHA ingredient global market in 2018 is estimated to almost triple by 2026 [11], further increasing overfishing pressure on anchovy and sardine stocks since anchovy/sardine oils are the dominant raw materials used to produce food and dietary supplement products.

The main production process currently employed to obtain fish oil omega-3 concentrate includes anchovy/sardine cooking and pressing on board the shipping vessel, followed by extensive chemical refining at omega-3 ingredient manufacturing sites [12].

Recently, simple and effective methods have been developed to sustainably source both olive polyphenols from olive and fish processing waste. In the case of olive phenolics, the process starts from olive mill wastewater, and employs citric acid to stabilize and progressively hydrolyze vegetation waters [13]. Extended to modern two-phase olive mills, the process affords olive phenolics aqueous extracts of unprecedented concentration [14].

In the case of anchovy fish oil, a new process starts from anchovy processing waste and uses citrus-derived α-limonene as extraction solvent in a closed loop process in which the biobased solvent is fully recycled affording an oil rich not only in EPA and DHA [15] but also in valued vitamin D₃ [16]. When compared to the multi-step conventional fish oil extraction and purification process, the new biobased circular process provides significant technical, economic and environmental advantages [17].

In this study, we show how combining sustainably sourced olive phenolic and omega-3 marine oil extracts may synergistically foster public health while providing substantial benefits to manufacturers of omega-3 and olive phenolics ingredients. Important educational outcomes for bioeconomy educators conclude the study.

2 The case for synergy between olive bi phenols and omega-3 lipids

An immediate advantage of using olive polyphenols in combination with omega-3 lipids is the enhanced chemical stability to PUFA tryglycerides abundant in marine oils.

This was shown by Spain’s scholars in 2008 reporting that hydroxytyrosol of 90-95% purity obtained by hydrothermal treatment of olive oil byproduct (olive mill wastewater, OMWW) added in 50 and 100 ppm to cod liver oil (40% of omega-3 lipids) was able to inhibit ω-3 lipids oxidation [18]. The higher oxidation inhibition was reached using 100 ppm HT (Figure 1).

![Fig. 1 Effect of hydroxytyrosol (Hyd) and propyl gallate (PG) at different concentrations (10, 50, and 100 ppm) on the formation of conjugated diene hydroperoxides in fish oil during oxidation at 40 °C. [Reproduced from Ref.18, with kind permission].](image)

Exerting neuroprotective, anti-inflammatory, anticancer and even antiviral (against several influenza A viruses [19]) activities, hydroxytyrosol abundant in Olea europea was recently found to be “the most actively investigated natural phenol” [20].

The compound has limited antibacterial activity [21], but its great pharmacological potential is widely recognized [22]. For example, in late 2020, Italy’s scholars reported the human safety of an oral spray containing microencapsulated hydroxytyrosol developed with the aim to inhibit the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) endocytosis [23].

Showing evidence of industrial interest, a few months later a joint team including researchers from a large food company reported that OMWW is an excellent antioxidant to retard lipid oxidation in fish oil-enriched food products [24].

Noting how the antioxidant properties of OMWW in fish bulk oil had not been previously reported, the team showed how it is enough to add lyophilized OMWW in 1 wt% amount to tuna oil (5 wt% in medium-chain triglycerides oil) to inhibit the formation of hydroperoxides, hexanal, and t,t-2,4-heptadien al alcohol throughout the storage period (14 days) by 94.2, 96.5, and 100%, respectively. Volatile compounds hexanal and nonanal (oxidation products of n-6 PUFAs) and t,t-2,4-heptadienal (oxidation product of n-3 PUFAs) form during the storage of tuna oil, with hexanal being the main volatile formed during the storage.

2
When compared to several antioxidants including oregano and parsley, ethylenediaminetetraacetic acid (EDTA) and Trolox (a water-soluble α-tocopherol analogue), OMWW was found to be the best antioxidant (Table 1). Remarkably, the effectiveness of OMWW (as well as of parsley and oregano) as antioxidant was found to relate to the total phenol content and oxygen radical absorbance capacity (ORAC) but not to the iron(II) chelating activity.

In a complementary and straightforward approach, a marine oil rich in omega-3 lipids such as algae oil (AO) is directly mixed with extra virgin olive oil (EVOO) [25].

In detail, mixing a commercial AO with high concentration of n-3 PUFA (35% DHA, 20% EPA and 5% docosapentaenoic acid (DPA, C22:5n-3)) with a shelf-life of 1 month with EVOO with a minimum quantity of 60 mg/g of secoiridoids and 80% of oleic acid reduced the oxidation processes in a dose-dependent manner (Figure 2) throughout storage.

Eventually, after 10 weeks, the amount of n-3 PUFA in the commercial oil was reduced by about 30%. It was enough to mix the AO oil with EVOO in 50:50 ratio (Mixture III) to lower the reduction in PUFA amount to 20%. Eventually, in EVOO:AO 83:17 mixture the PUFA content after 10 weeks was reduced by less than 10%.

The team concluded that the addition of EVOO rich in polyphenols to marine oils is “a simple alternative for the stabilization of unstable oils rich in omega-3, facilitating their application in the industry” [25].

As mentioned above, synergy between olive polyphenols may extend well beyond the enhancement of omega-3 lipids oxidative stability.

For instance, as early as 2005 scholars in Brazil reported the outcomes of a clinical study showing that supplementation with olive oil in patients who had rheumatoid arthritis and were at the same time using fish oil supplements resulted in a more precocious and accentuated improvement when fish oil supplements were used in combination with olive oil [26].

The conventional industrial processes used to extract and purify fish oil [12] removes also the lipophilic polyphenols naturally present in the fish fat, including the powerful antioxidant and anti-inflammatory phlorotannins obtained by fish eating brown algae [27].

In 1986, studying the effect of eight weeks of daily intake of omega-3 lipids in the form of fish oil or omega-3 capsules, Østerud had found modest benefits on the activity of blood cells, suggesting that concentrate omega-3 did not have the same health effects as marine oils in natural form.

These preliminary findings were subsequently confirmed by numerous studies [28,29,30], suggesting that a daily fish intake more effectively enhances the plasma concentration of n-3 PUFA as compared with the intake of concentrated EPA and DHA ethyl esters in capsules.

Østerud and Elvevoll in Norway in the late 1990s first suggested that purification significantly lowers the health benefits of refined marine oils, freed of important natural antioxidants. In 2001 they reported at a congress held in Vienna the results of administering healthy volunteers with cold pressed versus refined marine oils. Better results, a consistent
improvement on parameters related to the development of cardiovascular disease were noted by supplementation with cold pressed seal oil, despite a lower content of \( n-3 \) fatty acids in the unrefined oil [29].

Three years before, studying the effect of intake of various marine oils on the number and volume of platelets in 266 healthy volunteers, the team reported that the combination of cod liver oil and olive oil produces better effects than the oils given separately [31].

A few years later, they were the first to recognize the commercial relevance of olive polyphenols to fish oil-based supplements applying for a patent describing the combination of seal oil and cold-pressed virgin olive oil [32]. The new combined oil was dubbed “Olivita”.

A clinical study was carried out during which healthy subjects were given 15 mL/day of combined cold pressed olive oil with refined seal or fish oil for 10-14 weeks. The recombined oils regained the properties lost during refining with clear anti-inflammatory effects seen in reduction of MCP-1 (monocyte chemotactic protein-1), C-reactive protein (CRP), as well as thromboxane \( \text{B}_2 \) and leukotriene \( \text{B}_4 \) assuming the seal oil combined with olive oil, and reduction in cytokines lost during refining with clear anti-inflammatory effects seen in reduction of MCP-1 (monocyte chemotactic protein-1), C-reactive protein (CRP), as well as thromboxane \( \text{B}_2 \) and leukotriene \( \text{B}_4 \) assuming the seal oil combined with olive oil, and reduction in cytokines assumed to be mild to moderate [33]. In brief, the combined EVOO + marine oils behaved similarly to cold pressed marine oils, while said changes were not observed in fish and seal oils without added EVOO.

In light of these and previous findings, scholars today ascribe the absence of diabetes and coronary hearth disease in native Greenland Eskimos discovered by Bang and Dyerberg in the late 1960s and subsequently ascribed to high hematic levels of DHA and EPA abundant in seal and whale meat [34], also “at least partly… to their co-ingestion of phlorotannins” [35].

Indeed, the use of brown algal phlorotannins to prevent refined fish oil from rancification was proposed as early as of 1996 when scholars in China reported that the antioxidant activity of 1% high molecular weight phlorotannins extracted from \( Sargassum kelpmanianum \) was 2.6 times higher than that of 0.02% BHT (\( \text{tert}-\text{butyl}-4\)-hydroxytoluene), a commonly employed synthetic antioxidant [36].

Today an omega-3 dietary supplement consisting of omega-3 from seal oil, extra virgin olive oil obtained from Spain and vitamin D is produced in Norway and successfully commercialized across the world. The manufacturer recommends the intake of six capsules per day (and not 1 or 2 as it happens with omega-3 capsules using refined marine oils) because the omega-3 fatty acids are not concentrated [37].

This suggests that newly developed olive biophenol extracts may reduce the number of needed capsules while enhancing the amount of phenolic compounds whose benefits, as mentioned above, go well beyond simple antioxidant activity.

3 The case for concentrated olive biophenol extracts

Most extraction routes of olive polyphenols from different sources such as olive leaves or olive mill wastewater afford extracts with phenolics concentrations generally <20 wt%, and often <10 wt% [3]. A recently developed extraction and separation protocol for olive mill wastewater polyphenols, on the other hand, affords concentrated phenolic oils [38] ideally suited to be mixed with marine oils.

In detail, raw OMWW obtained from olive mills undergoes centrifugation and simple filtration to remove all solid particles after which it is acidified to \( \text{pH} \approx 2 \) with concentrated HCl, and defatted in a separatory funnel using \( n \)-hexane. The resulting aqueous layers are extracted with EtOAc to retrieve the phenolic molecules, after which the EtOAc extract is dried over anhydrous \( \text{Na}_2\text{SO}_4 \) and evaporated under vacuum affording a yellowish-brown crude oil.

Today an omega-3 dietary supplement consisting of omega-3 from seal oil, extra virgin olive oil obtained from Spain and vitamin D is produced in Norway and successfully commercialized across the world. The manufacturer recommends the intake of six capsules per day (and not 1 or 2 as it happens with omega-3 capsules using refined marine oils) because the omega-3 fatty acids are not concentrated [37].

This suggests that newly developed olive biophenol extracts may reduce the number of needed capsules while enhancing the amount of phenolic compounds whose benefits, as mentioned above, go well beyond simple antioxidant activity.

The same crude samples obtained from liquid-liquid extraction were purified also through a C18-reversed phase silica column packed in 9:1 acetonitrile:acidified water (2.5% w/w formic acid). The column was eluted with the latter eluent and then polarity was gradually increased up to 1:1 acetonitrile:acidified water in order to recover a biophenol fraction obtained as a yellowish oil (C18 purified polyphenol mixes, CPPM). The oils (Figure 3) have a virtually identical phenolics profile, with tyrosol and hydroxytyrosol as the main components (Table 2).

OMWW is a virtually unlimited source of these valued compounds. It is enough to quickly assess the amount of hydroxytyrosol and tyrosol contained therein and then to apply the aforementioned green commercial extraction process to OMWW batches with the highest amount of these polyphenols [41].

Anchovy oil extracted with citrus-derived d-limonene from anchovy filleting waste affords a natural (non-refined) oil rich in EPA and DHA [15], vitamin D3 [16] and natural astaxanthin (Figure 4). Found in several microalgae, fish and seafood species, the latter carotenoid is a powerful antioxidant and an important neuroprotective agent [42].

Even for this newly developed marine oil dubbed herein AnchoisOil, the addition of the new olive biophenol extracts described above would further protect the PUFA and astaxanthin from oxidation. At the same time, the intake of such a functionalized natural fish oil would results in cardoprotective action thanks to the olive biophenols integrated into the lipoproteins after entering the bloodstream protecting their lipid components from oxidation and exerting anti-inflammatory action at the artery walls [35].

Clinical studies will be necessary to demonstrate the synergy between this new marine oil and concentrated olive biophenols in the prevention of diseases such as coronarial hearth disease or in the cure (relieving) of common morbidities such as atherosclerosis, joint and muscle pain or psoriasis.

4 Conclusions and perspectives

Largely thanks to the pioneering studies of Østerud, it is now increasingly understood that supplementation of refined omega-3 polyunsaturated lipids in the form of ethyl esters may cause either limited effect on human blood lipids, platelets and coagulation [43] or even undesirable oxidative stress leading to increase in proinflammatory products [44].

Østerud and Elevoll suggest that the lack of cardiovascular disease and type 2 diabetes observed in the late 1960s by Dyerberg and Bang in native Greenlanders chiefly eating seal and whale blubber [34] has been due to the concomitant action of omega-3 lipids and the natural polyphenols contained in blubber protecting the unstable PUFAs from oxidation and autooxidation [45].

Adequate of the unique antioxidant power of olive polyphenols [4], the Norway’s scholars in the mid 1990s started to study the
clinical effects of mixing unrefined marine oils with extra virgin olive oil rich in phenolic compounds [31].

Eventually, the combination of marine oils and EVOO was patented [32] and new nutraceutical products based protecting against oxidative degradation and provided with further anti-inflammatory, anti-atherogenic and cardioprotective activities due to synergy between olive biophenols and omega-3 lipids were commercialized [37].

Subsequent advances in marine oil and olive biophenol extraction technologies have opened the route to the production of new nutraceutical and pharmacological products based on the combination of newly obtained natural marine oils and olive phenolics extracts.

In the case of marine oils, a new general strategy to obtain highly valued marine oils in their natural form, namely as tryglycerides containing plentiful natural antioxidants including astaxanthin, was demonstrated for both anchovy [15] and shrimp [46] waste (rather than from anchovy and shrimp) using biobased and biocompatible citrus limonene as recyclable extraction solvent.

In the case of olive phenolics, new green processes were demonstrated to readily obtain highly concentrated and pure phenolic extracts in two steps using liquid-liquid extraction followed by chromatography on hydrophobized silica [39,41].

In the era of overfishing [47] and with the global population rapidly ageing (22% of the world’s projected population is expected to be over the age of 60 years by 2050, from just 12% in 2015 [48]), these findings are of remarkable global relevance.

Rather than mixing olive and marine oils, the aforementioned natural marine oils obtained from overfished and mercury-free marine species, such as anchovy and shrimp processing waste will be further functionalized with small amounts of olive oil waste extracts rich in pluripotent biophenols such as hydroxytyrosol, tyrosol and oleocanthal.

Following clinical studies, the nutraceutical and pharmacological products based on the aforementioned combination of newly obtained natural marine oils and olive phenolics extracts will hopefully provide and expand the health benefits already observed via the combination of marine and olive oils.

New green chemistry technologies such as the green extraction and recovery of natural products summarized in this study for marine oils and olive phenolics actually behave as the key enabling technologies of the bioeconomy, with important educational consequences for green chemistry and bioeconomy educators using recent research achievements to foster student creativity [49].

Students indeed find in this case study another example of how also in biochemistry and in the bioeconomy progress in science is far from being linear, and requires the re-discovery of forgotten findings [50] such as those concerning the unique role of antioxidants in marine oils and the dangers associated with their removal during the production of refined fish oil to manufacture food and nutraceutical supplements [12,43,44,45].

As the chemical industry rapidly evolves towards biobased productions carried out in distributed chemical plants using green chemistry technologies [51], furthermore, students can learn how the production of marine oils and phenolic extracts at low cost enabled by the aforementioned green chemistry routes allows to expand their commercial utilization of fishery and agricultural waste in low-income and middle-income countries, meeting a key requirement of the bioeconomy for which highly valued functional substances are sustainably derived from renewable resources [52].
