## **Supplementary Material III**

Diagrams of successful modeling attempts with three functions of type (1)

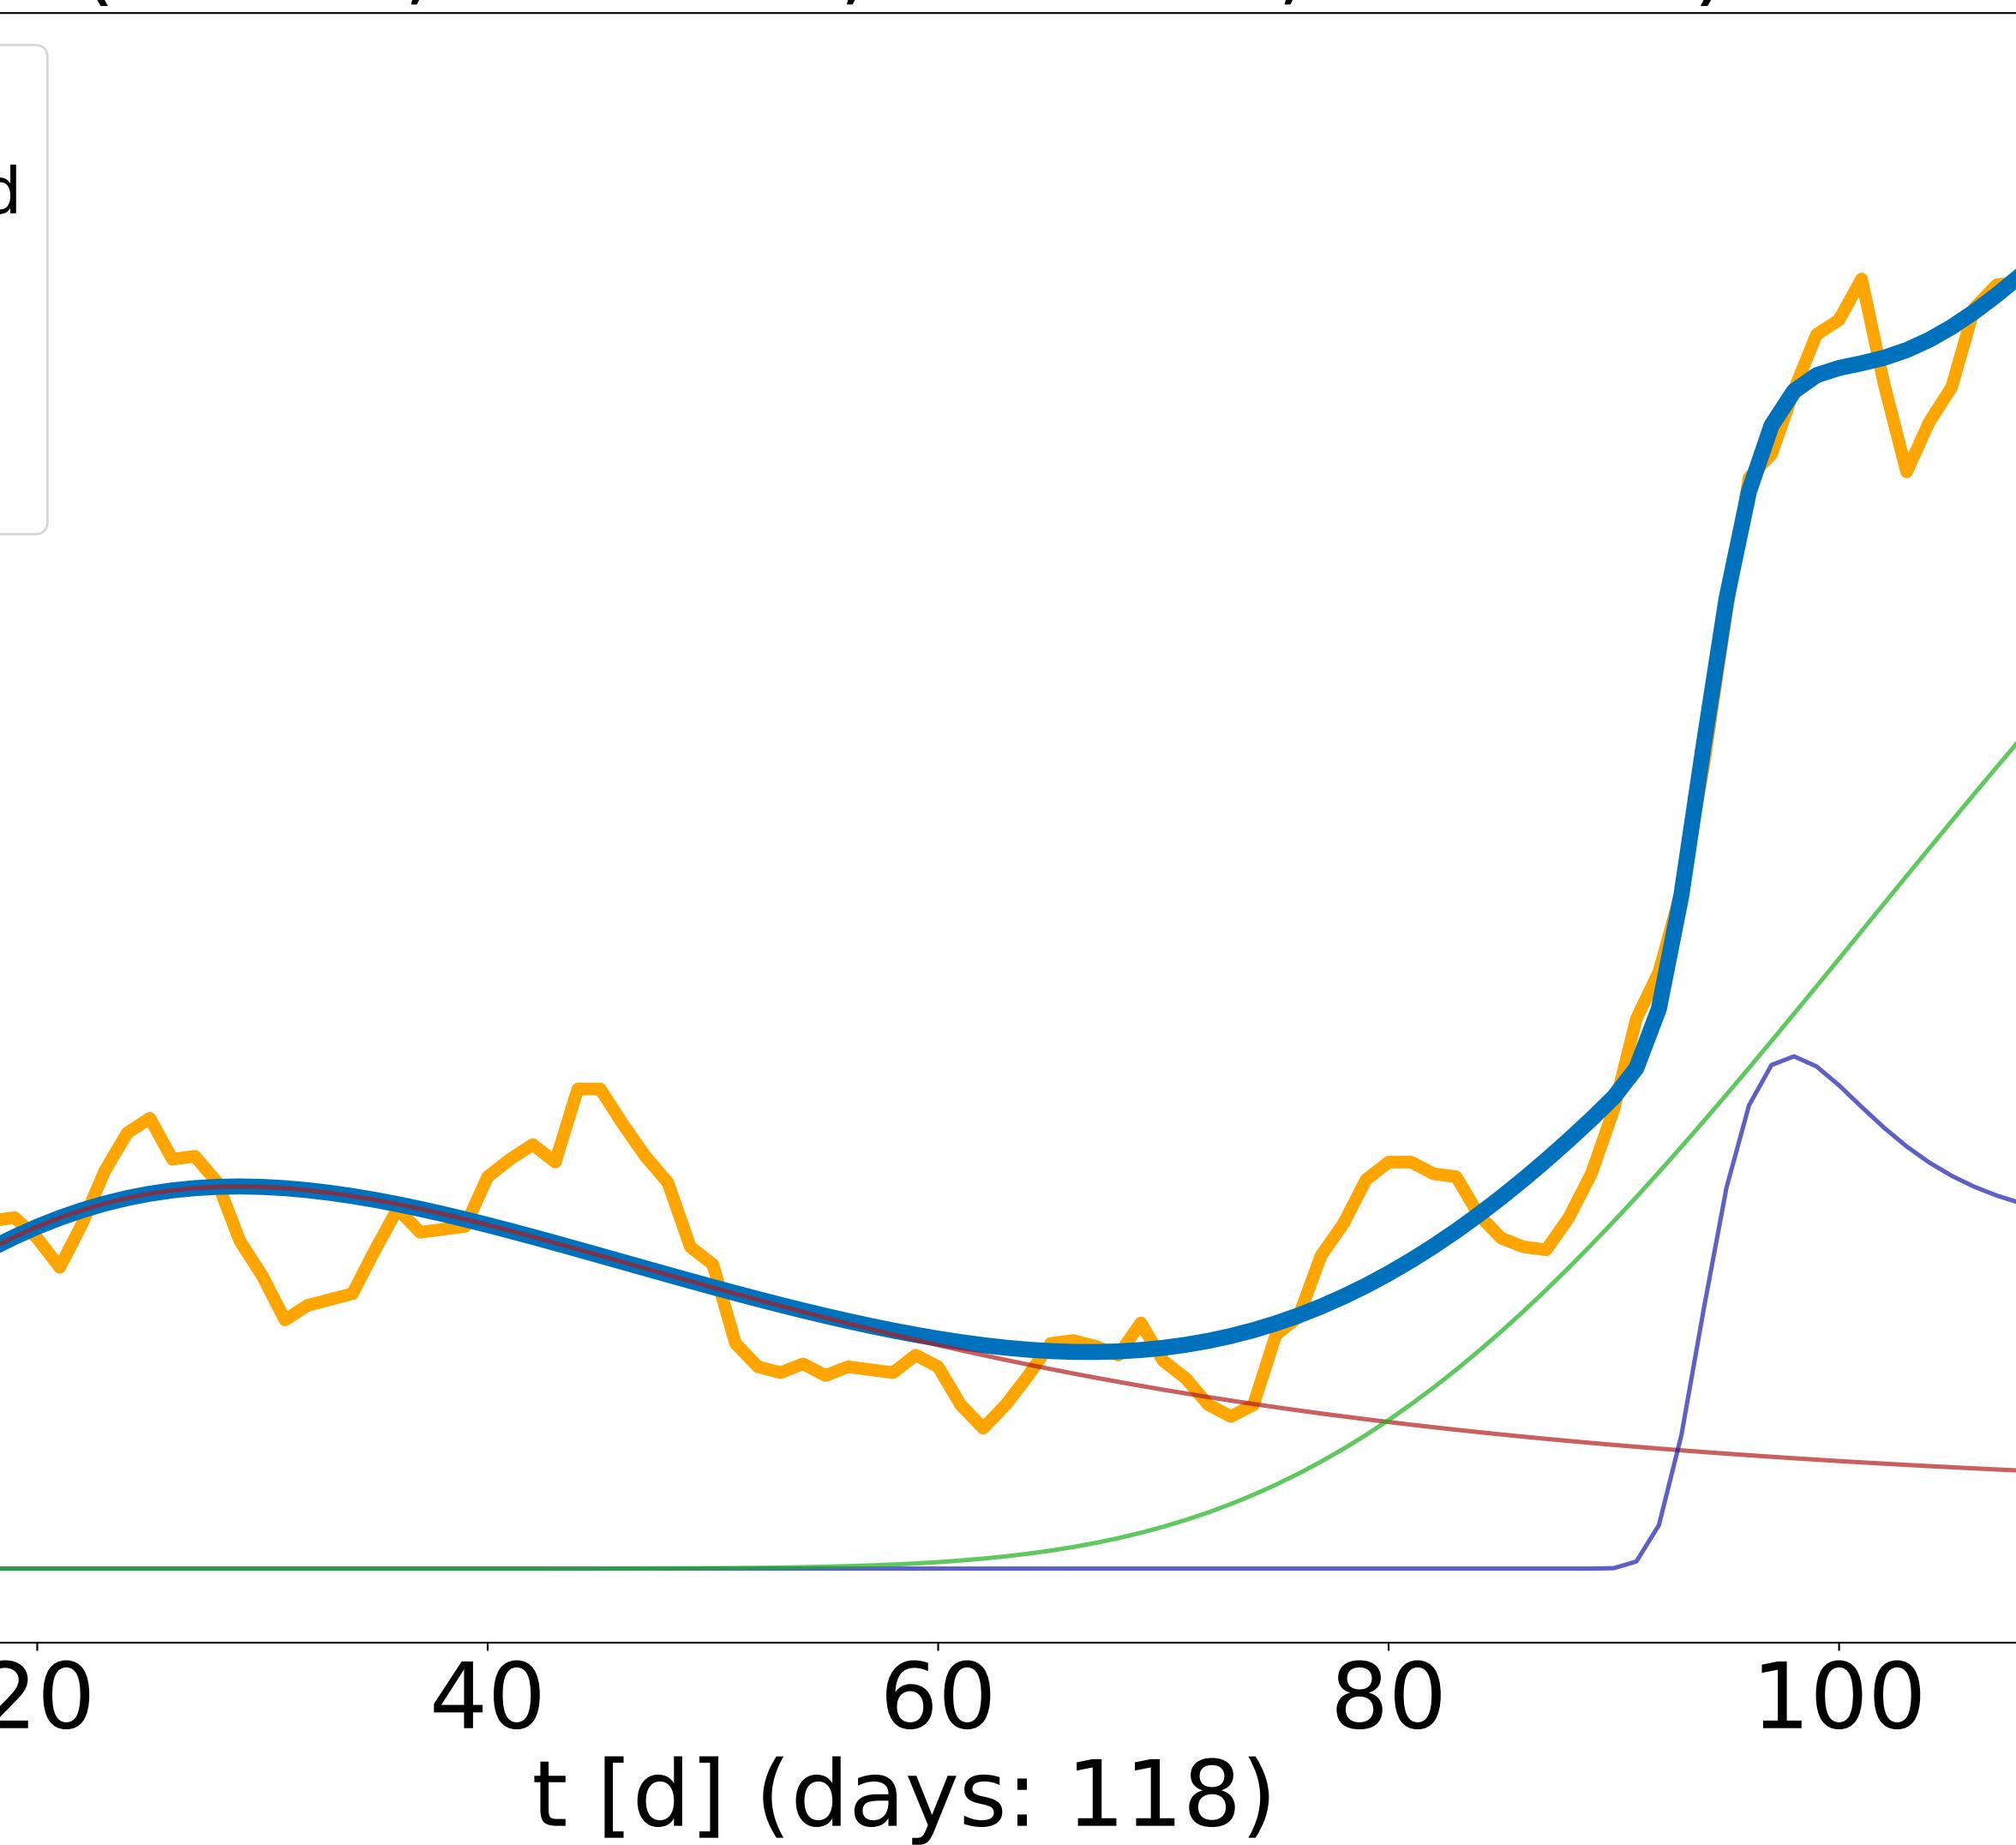

$$\hat{I}(t) = \hat{I}(0) e^{(ae^{-bt})t} \quad (1)$$

By an automatic procedure, daily infection number developments in all a) countries and b) US counties monitored by JHU [9] were modeled using a linear combination of three functions of type (1) (status: end of June, 2020). The diagrams of those modeling attempts leading to an  $R^2$  value (a)  $> 0.977$ , (b)  $> 0.970$ . The diagrams of those modeling attempts leading to an  $R^2$  value  $> 0.97$  (for the 7-days averaged data) are shown in the following. As in Fig. 1 of the paper, function parameters for raw data (left diagram) and for 7-days averaged data were determined separately (while for Fig. 2 parameters were determined for 7-days averaged data only).
