**Abstract:** Nutritional interventions have beneficial effects on certain psychiatric disorder symptomatology and common physical health comorbidities. However, studies evaluating nutritional literacy in mental health professionals (MHP) are scarce. This study aimed to assess the degree of self-rated training and literacy relating to nutrition in MHPs. We conducted a cross-sectional survey across 52-countries. Surveys were distributed via colleagues and professional societies. Data were collected regarding self reported general nutrition knowledge, nutrition education, learning opportunities, and the tendency to recommend food supplements or prescribe specific diets in clinical practice. In total, 1056 subjects participated in the study: 354 psychiatrists, 511 psychologists, 44 psychotherapists, and 147 MHPs in-training. All participants believed the diet quality of individuals with mental disorders was poorer compared to the general population ( $p < 0.001$ ). The majority of the psychiatrists (74.2%) and psychologists (66.3%) reported having no training in nutrition. Nevertheless, many of them used nutrition approaches, with 58.6% recommending supplements and 43.8%

recommending specific diet strategies to their patients. Only 0.8% of participants rated their education regarding nutrition as 'very good'. Almost all (92.9%) stated they would like to expand their knowledge regarding 'Nutritional Psychiatry'. There is an urgent need to integrate nutrition education into MHP training, ideally in collaboration with nutrition experts to achieve best practice care.

## 1. Introduction

People with psychiatric disorders frequently experience a decreased quality of life due to disability, comorbidity and stigma, and have a reduced life expectancy compared to the general population [1,2]. Psychiatric disorders are significant contributors to the global burden of disease and pose one of the most pressing current challenges [3]. Traditional treatment and management strategies for psychiatric disorders have suboptimal effectiveness, and typically focus on trying to lower symptomatology, meaning disorders are often persistent rather than transient. Further, individuals living with psychiatric disorders have a 15-year reduced life-expectancy compared to the general population [4], predominantly driven by high rates of cardiovascular disease, diabetes and metabolic syndrome [5]. Research on novel preventative and treatment strategies is of fundamental importance to reduce the burden of disease associated with the psychiatric disorder and common chronic disease comorbidities.

Nutritional psychiatry (NP) is an emerging field, with promising research suggesting a role for adjunctive nutritional approaches for the prevention and treatment of numerous neuropsychiatric disorders [6]. The notion that the availability of micro- and macronutrients is fundamental to brain development and function is well-established. More recently, evidence has highlighted the critical role dietary composition plays in influencing gut microbiota, neurotransmitters, neuropeptides, and the immune system, all of which are involved in the pathogenesis of psychiatric disorders [7-9]. Poor nutrition is considered a modifiable risk factor for general mental health and certain mental disorders. For example, eating five serves of vegetables and fruit is associated with better general mental health (increased optimism and self-efficacy and lower psychological distress and depressive symptoms) [10]. This relationship between dietary intake and mental health was strengthened by a recent meta-analysis of 16 randomized controlled trials (RCTs; n=45,826) which found that nutritional interventions significantly reduced depressive symptoms, particularly when they were delivered by accredited nutritional professionals (e.g., dietitians or nutritionists) [11]. The effects of nutrition intervention are comparable to behavioral therapy and superior to a 'social support group' in patients suffering from depression [12,13]. Given the inadequacies of traditional preventative, treatment and management strategies in psychiatry when used alone, greater importance should be placed on adjunctive strategies such as nutritional psychiatry [14,15].

Moreover, individuals with mental health problems frequently have an unhealthy lifestyle including poor dietary choices, disordered eating behaviours and nutritional deficiencies [16,17]. This is driving, in part, the high rates of chronic disease and reduced life expectancy [2]. Therefore, lifestyle modification (including diet) should be incorporated as best practice management of physical comorbidities in people with psychiatric disorders [18]. It is reassuring to note that the nutrition recommendations and dietary patterns for protecting peoples' physical health are in line with those which are beneficial for mental health.

It is critical that mental health professionals (MHPs) have basic training and literacy in nutrition so they can provide preliminary nutrition advice to patients and refer them to nutrition experts as necessary. However, the training, literacy level and use of nutrition approaches by key MHPs: psychologists and psychiatrists, remains unclear. European and US studies have investigated current nutrition training in general medical curricula

and found that nutritional medicine is either not taught, or insufficiently taught, in medical school [19-21]; however, there are some recent developments to integrate nutrition in medical education (e.g. PAN-int.org). Additionally, some universities have begun offering certifications in nutritional psychology, but there are no official regulations or standards.

To our knowledge, there is a paucity of studies on the perception, education, and awareness of psychiatrists, psychologists, and psychotherapists in relation to nutrition literacy and interventions. One small study (n=6) investigated subjective opinions of psychotherapists regarding nutrition [22] and suggested that dietary issues should become more integrated into the field of psychotherapy. In a survey from 1989, 232 American psychologists reported that they received no education regarding nutrition, but more than half of the participants believed that diet and exercise should be a mandatory component in the graduate school curriculum [23]. No newer studies on this subject were identified by the authors. Based on the existing curricula, a large educational gap regarding nutritional education is still foreseeable.

Thus, we formulated the following hypotheses: (1) MHPs globally have engaged in little-to-no nutrition education and self perceived nutrition literacy is low as nutrition approaches are not taught in graduate or postgraduate MHP courses, (2) Nutrition care is not integrated in routine clinical practice as nutritional literacy is low, and (3) Nutrition interventions (i.e., diet or supplements) are not applied in clinical practice. The aim of this study is to investigate: level of nutrition education taught in university programs, self-perceived nutrition literacy and use of nutritional approaches (diet and/or supplements) in clinical practice.

## 2. Materials and Methods

### *Recruitment of participants and group characteristics*

The online-survey was approved by the ethics committee of the Medical University of Graz, Austria (No: EK 31-021ex 18/19). Data were acquired using an anonymous, self-rated questionnaire accessible via Google forms (<https://www.google.com/forms/about/>). The questionnaire was distributed via email to national and international colleagues using a combined snowball-sampling approach. All psychiatrists of Austria received an invitation to participate via the Austrian medical chamber. Psychiatrists and psychologists worldwide were contacted through the early career psychiatrists (ECP) network of the World Psychiatric Association (WPA) and local professional psychiatric associations.

Participants provided informed consent electronically before participation. The informed consent page presented two options ('yes'/'no'). Only subjects who chose 'yes' were taken to the questionnaire page, and participants could end their participation at any time.

Inclusion criteria were as follows: (i) psychologists, psychiatrists, psychotherapists as well as psychologists in training and psychiatrists in training (psychiatry registrars), (ii) aged between 24 and 100 years, (iii) gave their informed consent to take part in the online survey, and (iv) ability to sufficiently understand the online questionnaire (which was available in English and German languages). Exclusion criteria were: (i) aged <24 years, given 24 is generally the minimum age to finish medical school/university and start a career in psychiatry or clinical psychology, and (ii) medical doctors in other specialties.

### *The Online Survey*

The survey was developed by a consensus approach between the lead authors. Participants received a standard, non-personalized online link via email, granting them access to the content of the survey. The survey could be completed via computer, tablet or smartphone and took approximately 10-15 minutes to complete. No pre-registration was required by participants. Following the consent page, the survey consisted of: demographic data, perceived importance of nutritional care, self-rated knowledge and formal education as well as current use in clinical practice. Questions were answered on a 10-point Likert scale from 1 (very low) to 10 (very high). A 10-point Likert scale was used as

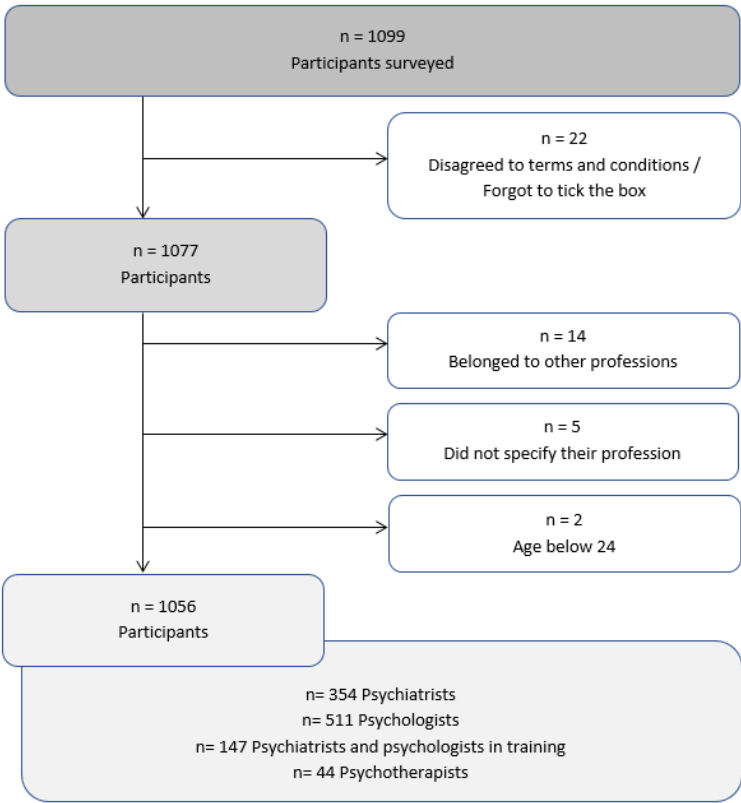

it offers more variance than the traditional 5-point likert scales and higher measurement precision and greater opportunity to detect subtle differences [24]. Survey questions can be accessed in the supplementary files (Supplementary File 1).

*Statistical evaluation and data management*

The analyses were conducted in SPSS v23.0 (IBM, Paris, France). Data-visualization was performed using Microsoft Excel 365 (Microsoft Corporation, Redmond, USA). Unless stated otherwise, descriptive results of continuous variables are expressed as mean and standard deviation (SD) for Gaussian distributed variables. Data of Likert scales are expressed as Median (Mdn) and Interquartile Range (IQR). Depending on the distribution of data and type of data, we performed an ANOVA, Student’s t-test, Mann-Whitney U test, or  $\chi^2$ -test to identify differences between professional groups. Professional subgroup analyses were conducted for demographical data (sex, age, working experience), current perceptions of ‘Nutritional Psychiatry’ and current treatment practices. Correlations between variables (current rated knowledge, work experience, rated importance of ‘Nutritional psychiatry’ and rated ‘importance of discussion nutrition with patients’) were calculated with Spearman’s correlation coefficient. Missing survey data points were treated as system missing values in SPSS unless otherwise specified. Results for post-hoc tests were corrected with the Bonferroni correction for multiple comparisons. Levels of statistical significance were set at  $p<0.05$ .

**3. Results**

Data were collected for a total of 22 months (from December 2018 to September 2020). Participants who did not agree to the terms and conditions (n= 22) and those who did not meet inclusion criteria (n= 21) were excluded from the analysis. The remaining participants (n=1,056) were included in the data analysis. When someone had several professions (for example being a psychiatrist and a psychotherapist) the reported main profession (psychiatrist) was counted. Figure 1 gives an overview of the flow of participants through the study.

**Figure 1.** Overview of participants surveyed.

3.1. Demographical Data of Study Participants

A final sample of 1056 participants: 354 psychiatrists, 511 psychologists, 147 psychiatry and psychology trainees, and 44 psychotherapists, from 52 countries were included. The majority of the participants were female (71.9%), and the mean age was 39.9 (SD 10.0) years.

The majority of participants reported working in a hospital (n=450, 42.6%), followed by private practice (n=233, 22.1%), mental health outpatient services (n=178, 16.9%), rehabilitations centres (n=64, 6.1%) and day clinic (n=20, 1.9%). A further 10% reported working in institutions other than those listed above, and one participant did not specify there place of work.

Table 1 gives an overview of the participant’s country of occupation, grouped by country income level. Of those who reported their country (n=1,047), most were based in high-income countries (n=905, 86.4%), followed by upper-middle income countries (n=121, 11.6%), lower-middle income countries (n=20, 1.9%) and 1 (0.1%) from a low income country. By region, most participants were in Europe (31 countries, n=866, 82.7%), followed by Asian (10 countries, n=108, 10.3%), North America (3 countries, n=34, 3.2%), Oceania (1 country: Australia, n=19, 1.8%), South America (3 countries, n=12, 1.1%) and Africa (4 countries, n=8, 0.8%).

**Table 1.** Income levels, country, and number of psychiatrists/psychologists working in the mental health sector.

Income group (June 2020)	Country	Continent	Participants (per country)	Psychiatrists working in mental health sector (per 100,000 popu- lation)	Psychologists working in mental health sector (per 100,000 popu- lation)

Data given in bold are the numbers of participants from each country who participated in the survey. Data given in italics is derived from World Health Organization (WHO): GHO | By category | Human resources - Data by country. (2019). Retrieved 23 November 2020, from <https://apps.who.int/gho/data/node.main.MHHR?lang=en>; \*Data source: Austrian Medical Chamber, 2020 \*\*Data source: Federal Ministry of Austria, List of health psychologists according to § 17 Psychologengesetz 2013, BGBl. I Nr. 182/2013 and List of clinical psychologists according to § 26 Psychologengesetz 2013, BGBl. I Nr. 182/2013, from <https://www.sozialministerium.at/Themen/Gesundheit/Medizin-und-Gesundheitsberufe/Berufslisten.html>. \*\*\* Data source: The College of Psychiatrists of Ireland Workforce Planning Report 2013 – 2023 December 2013. From <https://www.irishpsychiatry.ie/wp-content/uploads/2016/10/CPsychI-Workforce-Planning-Report-2013-2023-Dec-2013.pdf>; \*\*\*\*data source: OECD (2014), "Psychologists per 100 000 population, 2000 and 2011 (or nearest year available)", in Making Mental Health Count: The Social and Economic Costs of Neglecting Mental Health Care, OECD Health Policy Studies, OECD Publishing, Paris, <https://doi.org/10.1787/9789264208445-graph36-en>.

Countries with the largest participation were: Austria (n=481), Romania (n=54), Israel (n=52), Germany (n=40) and Serbia (n=35). Figure 2 illustrates the degree of participation by country.

**Figure 2.** World map showing all participating countries. Light gray color indicates countries with few participants; dark gray color indicates countries with numerous participants. This map was created with Microsoft Excel® (own figure).

Participants were specialized in general adult psychiatry or psychology (n=467, 44.2%), child and adolescent psychiatry or psychology (n=151, 14.3%), neuropsychiatry or neuropsychology (n=54, 5.1%), psychosomatics (n=49, 4.6%), psychogeriatrics (n=36, 3.4%), addiction medicine (n=22, 2.1%) and forensic psychiatry or psychology (n=15, 1.4%). According to 72 (6.8%) participants, their specialization was not listed, a further 154 (14.6%) reported to have no specialization and 35 (3.4%) gave no answer.

Table 2 gives an overview of participants and comparisons of main characteristics between psychiatrists, psychologists, and psychotherapists.

**Table 2.** Main characteristics of participants according to their profession.

		PsychiatristsPsychologists		Psychothera- pists	Psychiatrists and psychologists in training	p-value
		(n= 354)	(n= 511)	(n= 44)	(n= 147)	
Sex (female)	n	193	428	34	102	<0.001
	%	54.5	84.3	77.3	69.4	
Age (years)	mean	40.9	42.1	40.2	30.5	<0.001
	standard deviation	11.1	10.5	11.5	4.6	
Working experi- ence (years)	mean	12.1	10.9	10.2	13.9	<0.001
	standard deviation	9.9	9.4	8.8	9.5	

Sex differed significantly across all groups ( $X^2(6, N = 1054) = 100.0, p < 0.001$ ). While approximately half of the psychiatrists were male, psychologists and psychotherapists were predominantly female (Table 2). Furthermore, groups differed significantly regard-

ing age ( $H(3) = 172.07, p < 0.001$ ), with psychologists being slightly older than both psychiatrists and psychotherapists (*both*  $p$ 's  $< 0.05$ ). As expected, psychiatrists and psychologists were significantly older than those in training ( $p < 0.001$ ). Additionally, a significant difference in the work experience between the groups was found ( $H(3) = 18.185, p < 0.001$ ). There was a significant difference in the duration of working experience between participants in training and all other groups: psychologists and participants in training ( $p < 0.001$ ), psychiatrists and participants in training ( $p = 0.012$ ), psychotherapists and participants in training ( $p = 0.011$ ).

In relation to the year of postgraduate education, 304 (28.8%) participants had specified their current year of postgraduate education, 561 (53.2%) participants had completed their studies and 191 (18.2%) did not specify.

### 3.2. Nutritional education

Of the 511 psychologist participants, 51.1% ( $n=261$ ) responded as to whether they received nutrition education during postgraduate studies: 173 (66.3%) reported no lectures, 59 (22.6%) reported some training during their studies in psychology, 22 (8.4%) attended electives on this topic and seven (2.7%) had obligatory courses (Austria  $n=6$  and Germany  $n=1$ ). Of the 354 psychiatrist participants, 198 (55.9%) psychiatrists responded to the question of whether they had specific training in the nutritional care of patients during their psychiatric residency: 147 (74.2%) psychiatrists reported no lectures, 30 (15.2%) had some training during their diploma of medicine and 17 (8.6%) completed electives on this topic. A minority of participants ( $n=4, 2.0\%$ ) had obligatory courses (Lithuania  $n=1$ , Switzerland  $n=1$ , UK  $n=1$  and USA  $n=1$ ). While working as a psychiatrist or psychologist, 111 (10.5%) participants had attended specific training in nutritional care.

Regarding awareness of courses that teach nutrition, 229 (21.7%) participants were aware of courses that teach nutrition for prevention and treatment of psychiatric disorders in their country or at their institution: 94 (41.1%) psychologists, 80 (34.9%) psychiatrists, 45 (19.7%) in training and 10 (4.4%) psychotherapists.

Nearly all participants (92.9%) would be willing to expand their knowledge of 'Nutritional Psychiatry'. The most popular avenue of learning was 'congresses' ( $n= 650$ ), followed by 'scientific journals' ( $n= 495$ ), and 'interdisciplinary meetings' ( $n= 480$ ). The least popular avenue was engaging in 'Master studies' ( $n= 80$ ) and 'Ph.D. projects' ( $n= 59$ ).

There were significant positive correlations between perceived current knowledge in 'Nutritional Psychiatry' and the following outcomes: i) participants perceived ability to improve their quality of work and participant outcomes by training in 'Nutritional Psychiatry' ( $r_s = 0.329, p < 0.001$ ), ii) rating of the importance of 'Nutritional Psychiatry' ( $r_s = 0.393, p < .001$ ), and iii) rating for importance of discussing nutrition with patients ( $r_s = 0.396, p < .001$ ).

### 3.3. Treatment practices

Two-hundred and thirty eight (67.2%) psychiatrists, 335 (65.6%) psychologists and 29 (65.9%) psychotherapists reported using nutritional approaches for the treatment of patients; with no significant differences between the professional groups ( $X^2(3, N = 1056) = 0.556, p = 0.906$ ).

Nutritional approaches were most frequently used for the treatment of eating disorders ( $n= 436$  answers) and affective disorders ( $n= 344$  answers), followed by anxiety disorders ( $n= 208$  answers), psychotic disorders ( $n= 130$  answers), and obsessive-compulsive disorders ( $n= 58$  answers). One third ( $n=379$  (35.9%)) of the participants reported having never used a nutritional approach for any psychiatric disorder. For the prevention of somatic comorbidities, 402 participants (38.1%) reported using nutritional interventions occasionally, while 212 (20.1%) reported never using such interventions, and only 43 participants (4.1%) always included nutritional interventions.

Nearly a quarter of the participating psychiatrists ( $n=88$ ; 24.9%) reported considering the individual nutritional status of patients when prescribing psychopharmacological therapy intermittently, 67 (18.9%), reported considering it most of the times and 22 (6.2%)

reported considering it always. 83 (23.4%) reported to never, and 62 participants (17.5%) to hardly ever consider the nutritional status of patients when prescribing psychopharmacological medication.

The most recommended lifestyle intervention was physical activity ( $n=935$ ), followed by dietary coaching ( $n=558$ ) and cooking classes ( $n=112$ ), while 102 participants reported hardly ever recommending lifestyle intervention. Most participants reported never ( $n=498$ , 47.2%) or hardly ever ( $n=306$ , 29.0%) testing for food allergies, gluten-sensitivity or food intolerances. There was no difference between the professional groups ( $X^2(12, N=1009)=8.058, p=0.781$ ).

Nutritional care in the context of mental disorders was considered as 'very important' by 121 (11.4%) of the participants (Likert scale 10/10). Discussing nutrition in the clinical setting was rated as very important (Likert scale 10/10) by 73 (6.91 %) of the participants.

When asked about rating the nutrition of the countries population the most frequent rating was 5/10 ( $n=199$ , 18.8%), only 6 (0.6%) rated the status as "very good" (Likert scale 10/10). When asked about the nutritional status of individuals with mental disorders in their country, the most frequent rating was 3/10 ( $n=294$ , 27.8%), only 1 person (0.1%) rated the quality with 'very good'. Importantly, participants rated the dietary quality of individuals with mental disorders ( $Mdn=3.00$ ) as significantly worse when compared to the general population ( $Mdn=5.00$ ) of their countries ( $U=265739.00, p<0.0001$ ). Participants most frequently rated the quality of food served in hospitals within their country of occupation as 5/10 ( $n=199$ , 18.8%). There was no significant difference between the qualification groups ( $H(3)=1.841, p=0.606$ ).

Regarding regular screening for comorbid metabolic disorders, 314 ( $n=29.7\%$ ) were aware of regular screening in their place of work, whereas nearly half of the participants did not know or provided no answer ( $n=469$ ; 44.4%) and 264 (25.0%) were unaware of regular screening. Interestingly, there was a significant difference between the professions ( $X^2(6, n=1047)=22.31, p=0.001$ ). After Bonferroni-correction for multiple testing, psychiatrists ( $p=0.006$ ) and psychologists ( $p=0.006$ ), as well as psychotherapists were significantly more aware of metabolic screening in their countries compared to those in training.

### 3.4. Recommendation of Diets and Dietary Supplements by MHPs

Nearly half ( $n=462$ ; 43.8%) of participants have recommended a specific diet to their patients. Participants could tick one or multiple boxes and had to choose from the following diets: diet in accordance with national guidelines, Mediterranean diet, vegetarian diet, vegan diet, ketogenic diet, low carb diet, Glyx diet, and/or other diets. The most recommended diets were Mediterranean diet ( $n=210$ ) and diet in accordance with national guidelines ( $n=202$ ), followed by low-carb diet ( $n=135$ ) and others ( $n=104$ ). Glyx diet ( $n=15$ ) and vegan diet ( $n=17$ ) were the least recommended. Table 3 and 4 provide an overview of other diets that could be given in a free text answer field. When asked to specify the indications for recommending the diet (multiple answers were possible) most of the participants named 'metabolic comorbidities' ( $n=421$ ), followed by 'prevention of adiposity' ( $n=387$ ) and 'obesity' ( $n=330$ ). For psychiatric indications, 'Eating disorders' ( $n=337$ ) was ranked first, followed by 'symptoms of depression' ( $n=282$ ), 'symptoms of anxiety' ( $n=159$ ), and ADHD ( $n=140$ ). Almost half of the participants ( $n=520$ , 49.2%) reported having already started a diet themselves and maintained it for at least one month. There was no significant difference between professional groups ( $X^2(3, N=1036)=3.904, p=0.272$ ) and no significant difference between male and female MHPs ( $X^2(2, N=1034)=3.246, p=0.197$ ).

**Table 3.** List of diets recommended by psychiatrists, psychologists, psychotherapists and psychiatrists/psychologists in training.

<i>Recommended Diet</i>	<i>Description</i>
<i>Alkaline diet/ Base-fasting</i>	Only foods that have a supposed alkaline metabolism are allowed for a preset period of time
<i>Blue Zone diet</i>	Low meat intake, high fiber and minimally processed foods, originating from so-called 'Blue zones' described as being healthiest communities worldwide [25]
<i>Chrononutrition</i>	Nutrition considering the circadian system [26]
<i>Clean 9</i>	Diet using a supplement regime
<i>Dietary advices based on macrobiotic diet</i>	A basic nutritional scheme which is individualized depending on sex, age, level of activity, individual needs and environment [27]
<i>Elimination reintroduction trials</i>	Individuals forgo certain foods or ingredients to find out if they have a negative effect on them
<i>F. X. Mayr Kur fasting</i>	Detoxifying diet originally with bread rolls and milk [28]
<i>FDH (= "Friss die Hälfte")- diet</i>	German phrase saying "eat half" (of what you normally would eat)
<i>FODMAP</i>	Restriction of rapidly fermentable, short-chain carbohydrates for patients with functional gut symptoms [29]
<i>Intermittent fasting</i>	Alternating time periods of regular food intake and fasting
<i>Metabolic balance diet</i>	Nutrition program aiming to change lifestyle permanently through individualized nutrition plans taking relevant blood parameters into account for laboratory support [30]
<i>MIND</i>	Mediterranean-DASH (Dietary Approaches to Stop Hypertension) Intervention for Neurodegenerative Delay [31]
<i>Nutrition according to the five elements</i>	Nutritional approach arising from traditional Chinese medicine. Local foods are categorized from an energetic point of view [32]
<i>Sleep diet by Dr. Pape</i>	Diet concentrating on eating the right thing at the right time and taking longer breaks between meals, in addition with an active everyday life and a lot of sleep [33]
<i>TCM (Traditional Chinese Medicine)</i>	TCM aims to achieve harmony and balance in one's body through food. It has its own internal logic and concepts [34]
<i>in general</i>	balanced, diversified healthy unprocessed seasonal, regional reasonable with regard to carbs traffic light system - diet (foods are labeled in different groups according to their amount of health-relevant nutrients)
<i>effects</i>	deacidifying warming dishes sleep promoting acid-base balance
<i>high / rich in</i>	whole foods

<i>inclusion of</i>	(plant based) fresh fruit and vegetables
	nuts
	fiber
	omegas
	proteins
	antioxidants
	fatty fish
	Probiotic food such as fermented cabbage
	serotonin rich food
<i>free of or reduction of</i>	gluten
	casein
	caffeine / soft drings with caffeine
	wheat
	dairy
	allergenic foods
	meat
	sugar / sweets
<i>reduction of</i>	calories
	portion quantity
	instant meals
	conservats
	cholesterol
	salt
	fat
	sodium
<i>free of</i>	sodium-glutamate
	alcoholic foods

**Table 4.** List of dietary specifications recommended by psychiatrists, psychologists, psychotherapists and psychiatrists/psychologists in training.

<b>depending on time</b>
regular nutritional intake
intermittent fasting
no stimulating foods in the evening
two meals a day
<b>depending on the process of the intake</b>
mindful eating
awareness of nutrition
no eating for stress relief

adapted to individual requirements	
diabetes	diabetes diet
eating disorders	diet plans, main and in-between meals
malnourished	fortification
obesity	hypocaloric diet
cachexia	high calorie intake
hyponatremia	salty nutrition
depending on specific cancer	
suspected serotonin side effects	avoiding foods with tryptophan
Morbus Wilson	low copper in nutrition
old people having difficulties with eating, anxious about it	especially eating what gives them pleasure
intake of monoamidoxidase (MAO-) inhibitors	low diet low in tyramine
Others	
Referral to colleagues	Nutritionist
	Dietologists
not qualified to give advice	
evidence-based	
slim without diet	
lifestyle	not necessarily through diet
	sports
	ban of illegal drugs

Next, we asked all participants whether they recommended nutritional supplements to their patients. A total of 619 (58.6%) participants reported recommending nutritional supplements: 64.5% of psychologists (n=323), 57.2% of psychiatrists (n=198), 54.5% of psychotherapists (n=24), and 51.0% of psychologists and psychiatrists in training (n=74). There was a significant between profession difference ( $X^2$  (3, n= 1036)= 10.635,  $p= 0.014$ ). Psychologists recommended more supplements than psychotherapists ( $X^2$  (1, n= 397)= 8.571,  $p= 0.003$ ), statistically significant after Bonferroni-correction ( $p= 0.018$ ). The higher rates of psychologists recommending supplements compared to psychiatrists ( $X^2$  (1, n= 521)= 4.538,  $p= 0.033$ ); was not statistically significant after Bonferroni-correction for multiple testing ( $p= 0.198$ ). There were no significant sex differences regarding recommendation of supplements ( $X^2$  (2, N=1033)= 3.758,  $p= 0.153$ ).

We provided a list of commonly recommended supplements for mental health which could be ticked in the instance participants ever recommended them to their patients (vitamin D, omega-3, vitamin A, vitamin E, selenium, zinc, magnesium, vitamin B6, vitamin B12, folic acid, iron, N-acetylcysteine). For this question, it was possible to tick more than one box. The most recommended supplement was vitamin D (n= 446), followed by vitamin B12 (n= 414), omega-3 (n= 364), folic acid (n= 319) and vitamin B6 (n= 314).

An additional 164 participants (15.5%) reported recommending supplements not listed in the survey or gave additional answers. Table 5 lists the additional supplements recommended by participants.

**Table 5.** List of dietary supplements recommended additionally to Vitamin D, Omega 3, Vitamin A, Vitamin E, Selenium, Zinc, Magnesium, Vitamin B6, Vitamin B12, Folic Acid, Iron, N-Acetylcysteine by psychiatrists, psychologists, psychotherapists, psychiatrists/psychologists in training.

<i>Supplements and foods recommended by mental health professionals for psychiatric disorders</i>	<i>[Linnean name] / Description and supposed (psychiatric) effects</i>
<i>5- Hydroxytryptophane (5-HTP)</i>	Naturally occurring amino acid, chemical precursor of serotonin, long been used as a nonpharmacological treatment for depression [35]
<i>Adaptogenic herbs</i>	Substances used in traditional and herbal medicine with the aim of stabilization and promoting adaptation to environmental factors [36]
<i>Albumin</i>	Family of globular proteins, found in blood plasma
<i>Alkalisng supplements</i>	E.g. sodium bicarbonate
<i>Aloe vera juice</i>	Juice of [ <i>Aloe barbadensis</i> ]
<i>Amino acids (several) /Protein powder</i>	Precursor to neurotransmitters (tryptophane, tyrosine)
<i>Ashwagandha</i>	[ <i>Withania somnifera</i> ], herb with gamma-Aminobutyric acid (GABA-)ergic properties used in traditional medicine to reduce stress and enhance wellbeing [37,38]
<i>Astaxanthine</i>	Carotenoid with antioxidant and anti-inflammatory properties, produced by several freshwater and marine microorganisms, including bacteria, yeast, fungi, and microalgae [39]
<i>Beta- glucan</i>	Sugars found in cell walls of bacteria, fungi, yeasts, algae, lichens, and plants (barley, oats) [40]
<i>Bitter substances</i>	Substances found in vegetables and spices (e.g. radicchio, chicory, endive, cardamom, ginger) used to treat digestive issues in traditional medicine systems
<i>Calcium</i>	Essential element needed in large quantities, acting as an electrolyte with important functions in nerve conduction and building of bone mass.
<i>Cannabidiol (CBD)</i>	Phytocannabinoid, used for treatment of anxiety, cognition, movement disorders, and pain (with insufficient evidence) [41]
<i>Chamomile tea</i>	Tea made from dried flowers of [ <i>Chamaemelum nobile</i> ]; traditionally used as a supplementary approach to treat sleep problems and depression [42]

Cherries	<i>[Prunus cerasus]</i> , source of polyphenols and vitamin C with anti-oxidant and anti-inflammatory properties; shown to increase melatonin in a small randomized double-blind placebo controlled trial [43,44]
Chia seeds	Seeds of <i>[Salvia hispanica]</i> , novel food, under preliminary research for potential effects on health, but this work remains sparse and inconclusive [45]
Chlorella	<i>[Chlorella species]</i> ; single-celled green algae, consumed as a health supplement primarily in the United States and in Japan; with limited evidence for depression [46]
Choline	Essential nutrient for humans needed for the production of the neurotransmitter acetylcholine; dietary sources of choline and choline phospholipids include egg yolk, wheat germ, and meats, especially organ meats, such as beef liver [47]
Chromium	Chemical element, used as a dietary supplement, showing decreases of the sensitivity of 5-HT <sub>2A</sub> receptors [48]
Coenzyme Q10	Ubichinone, coenzyme, present in all cells, mainly in mitochondria as an element of the electron transport chain [49]
Copper	Chemical element, with high serum levels in Wilson's disease [50]
Epigallocatechin gallate (EGCG)	Abundant catechin in green tea; polyphenol, found to enhance sleep [51]
Evening primrose oil	<i>[Oenothera]</i> , containing gamma-linolenic acid
Feverfew	<i>[Tanacetum parthenium]</i> , medicinal herb, traditionally used for the prevention of migraine [52]
Ginkgo	<i>[Ginkgo biloba]</i> , used alone or as an add-on therapy, in the treatment of mild cognitive impairment and dementia [53]
Glycine	Amino acid, inhibitory neurotransmitter in the central nervous system, required co-agonist along with glutamate for N-methyl-D-aspartate (NMDA) receptors [54]
Green tea	<i>[Camellia sinensis]</i> , health benefits have been assumed throughout the history of using tea as a common beverage, no high-quality evidence shows that tea confers significant mental health benefits [55]
Griffonia	<i>[Griffonia simplicifolia]</i> ; a tropical plant native to West Africa, rich in 5-hydroxy-L-tryptophan (5-HTP), a precursor in the synthesis of serotonin (5-HT), traditionally used for the treatment of depression [56]

<i>Herbal medicines</i>	Traditional plant-derived medicines, often given in combinations
<i>Herbal mixture (7 herbs from Heidelberg) (anise, cumin, fennel, wormwood, yarrow, burnet, juniper)</i>	Traditional herbal mixture used in Germany (Heidelberg) for the treatment of digestive issues
<i>Huperzine</i>	Alkaloid compound found in [ <i>Huperzia serrata</i> ], with effects on improvement of cognitive function, daily living activity, and global clinical assessment in Alzheimer's disease [57].
<i>Inositol</i>	Carbocyclic sugar, abundant in the brain and important for cell signal transduction in response to a variety of hormones, neurotransmitters, and growth factors, osmoregulation; used for panic disorders and obsessive compulsive disorders [58,59]
<i>Iodine</i>	Chemical element; used to treat iodine-deficiency or thyreotoxicosis
<i>Kudzu / Japanese arrowroot</i>	[ <i>Pueraria montana</i> ] trailing perennial vines native to East Asia / food supplement traditionally recommended for the treatment of alcohol abuse and dependence [60,61]
<i>L-Arginine</i>	Amino acid that is used in the biosynthesis of proteins with possible roles in atherosclerosis, redox stress and the inflammatory process, regulation of synaptic plasticity and neurogenesis, and modulation of glucose metabolism and insulin activity.[62,63]
<i>L-Aspartate</i>	Amino acid that is used in the biosynthesis of proteins
<i>Lavender oil</i>	[ <i>Lavandula</i> ], herbal oil traditionally used for anxiety and sleep disturbances [64,65]
<i>Lecithin</i>	Group of yellow-brownish fatty substances occurring in animal and plant tissues, used as a dietary supplement for dementia, with no found benefits [66]
<i>Lemon balm</i>	[ <i>Melissa officinalis</i> ]; used as a sleep-aid in traditional medicine; anxiolytic, effects on mood, cognition and memory have been shown in clinical trials. AChE inhibitory activity, stimulation of the acetylcholine and GABA-A receptors and matrix metallo proteinase-2 are potential mechanisms of action [67,68]
<i>L-Lysine</i>	Essential amino-acid in humans; found to reduce positive symptoms in schizophrenia in small pilot trials; reduced anxiety and improve stress response [69,70]
<i>L-Methylfolate</i>	Primary biologically active form of folate; adjunctive antidepressant effect in major depressive disorder [71]

<i>L-Ornithine</i>	Non-proteinogenic amino acid, found to relieve stress and improve sleep quality related to fatigue [72]
<i>L-Theanine</i>	Amino acid analogue of the proteinogenic amino acids L-glutamate and L-glutamine, constituent of green tea; decreased anxiety, along with benefits to sleep quality in attention deficit hyperactivity disorder (ADHD) [73,74]
<i>L-Tryptophan</i>	Amino acid that is used in the biosynthesis of proteins; converted into 5-hydroxytryptophan (5-HTP) which is then converted into serotonin and melatonin; dietary supplement used antidepressant, anxiolytic, and sleep aid with limited evidence for depression [75]
<i>Melatonin</i>	Hormone of the pineal gland which regulates the sleep–wake cycle with antioxidant properties; improves sleep and has an anti-depressant effect [76]
<i>Methylsulfonylmethane (MSM)</i>	Organosulfur compound; used in alternative medicine with no known medical benefits for psychiatric disorders, which crosses the blood-brain-barrier [77,78]
<i>Mineral tablets</i>	Common constituent of dietary supplements
<i>Mint tea/Peppermint</i>	Herbal infusion of [ <i>Mentha piperita</i> , <i>Mentha spicata</i> ]; used in traditional medicine for irritable bowel syndrome (IBS) symptoms ; limited human studies, no clinical trials for psychiatric indications [79]
<i>Multivitamins</i>	A supplement containing a range of vitamins and/or dietary minerals.
<i>Passion flower</i>	[ <i>Passiflora L.</i> ] , traditionally used as a sedative and anxiolytic [80]
<i>Phosphorylethanolamine</i>	Ethanolamine derivative; found to have specific effects on mitochondrial function [81]
<i>Plum juice</i>	[ <i>Prunus spec.</i> ] traditionally used as a dietary laxative, anti-oxidant and anti-inflammatory properties [82]
<i>Polyphenols</i>	Naturally occurring organic compounds characterized by multiples of phenol units, possible improving cognitive performance and symptoms of depression [83,84]
<i>Potassium</i>	Given as potassium chloride used in the treatment of hypokalemia.
<i>Prebiotics (several)</i>	Non-digestible fiber, promoting growth of microorganisms; did not differ from placebo in trials for depression and anxiety in a recent meta-analysis [85], use of prebiotics still lacks sufficiently robust evidence for psychiatric disorders [86]

<i>Propolis</i>	Mixture of bees wax and saliva produced by honey bees; used in traditional medicine; possibly exhibiting antioxidant activity, and positive neurotrophic modulation [87]
<i>Pycnogenol</i>	Chemical compound found in the bark of European pine trees / <i>Pinus pinaster</i> subsp. <i>Atlantica</i> ; alternative nutritional supplement traditionally used for the treatment of attention-deficit-hyperactivity disorder (ADHD); one small open label study for antidepressant induced sexual dysfunction [88,89]
<i>Red clover</i>	[ <i>Trifolium pratense</i> ], herb containing phytoestrogens, shown to increase cognitive function in postmenopausal women [90]
<i>Rose root</i>	[ <i>Rhodiola rosea</i> ], adaptogen used for reduction of stress-related syndromes, such as fatigue and burnout [91]
<i>S-Adenosyl-L-Methionine (SAME)</i>	Co-substrate involved in methyl group transfers, transsulfuration, and aminopropylation, used as an add-on therapy for depression [92]
<i>Saffron</i>	[ <i>Crocus sativus</i> ], effective for symptoms of depression and anxiety [93,94]
<i>Salt (Sodiumchloride, NaCl)</i>	Used as saline solution for a number of indications in clinical medicine
<i>Seaweed oil</i>	Oil from macroalgae rich in phytosterols, carotenoids, and polysaccharides; extracts used in diet pills to lose weight; compounds cross the blood-brain barrier and exert neuro-protective functions [95,96]
<i>Silibinum</i>	[ <i>Silybum marianum</i> ] active compound from the milk thistle; traditionally used for hepatic disorders; plant based intervention for obsessive compulsive disorder and anxiety disorder [97]
<i>Sip foods</i>	Used as additional calorie sources in the treatment of anorexia nervosa
<i>Soy products</i>	Products made from soybeans [ <i>Glycine max</i> ]; may improve cognitive function in adults [98]
<i>St. Johns Wort</i>	[ <i>Hypericum perforatum</i> ], used for mild to moderate major depression, with moderate quality evidence and comparative effectiveness towards standard antidepressants [99]
<i>Tumeric, Curcumin</i>	[ <i>Curcuma longa</i> ], spice frequently used in Asian countries with anti-inflammatory and anti-oxidant properties with effects on depressive and anxiety symptoms [100]
<i>Tyrosine</i>	Amino acid, precursor of dopamine and noradrenaline, thyroid hormones, and melanin; reverses cognitive decline under stress or cognitive demands [101]

Valerian	[ <i>Valeriana officinalis</i> ], GABA-modulating phytochemical used as an anxiolytic [102]
Vitamin B1	Thiamine, used for prevention of Wernicke-Korsakoff-syndrome in alcohol dependency disorders [103]
Vitamin B3	Vitamin family that includes three forms or vitamers: nicotinamide (niacinamide), niacin (nicotinic acid), and nicotinamide riboside; deficiencies cause pellagra (fatigue, loss of appetite, abdominal pain), co-factor in serotonin-synthesis [104]
Vitamin B-Complex	Complex of water-soluable B-vitamins in food supplements
Vitamin C	Co-factor in serotonin-synthesis, with deficiencies linked to depression and cognitive impairment [105]
Vitamin K2	May be beneficial for prevention of bone loss in patients with anorexia nervosa; reduced anxiety and depression in murine models [106,107]
Wild yams	[ <i>Dioscorea villosa</i> ]; traditionally used root containing phytoestrogens; reduced anxiety and other menopause symptoms in one murine study; no human studies [108]
Zeolite	Aluminosilicate minerals used as adsorbents; ongoing in-vitro and in-vivo experiments regarding attention-deficit- hyperactivity disorder (ADHD); no clinical studies [109,110]

\* In the case of someone recommending a specific brand name, the active ingredient is given in the table. In instances where an herbal supplement was mentioned, the Linnean classification of the herb is given in brackets.

Most participants (n=853, 79.1%) reported taking, or having taken, supplements themselves, while 206 participants (19.5%) reported never having taken supplements, and 15 (1.4%) gave no answer. There was no significant between profession difference ( $X^2$  (3, N =1041) =5.384,  $p= 0.146$ ), or between gender difference ( $X^2$  (2, N =1038) = 3.504,  $p= 0.173$ ) for supplement intake.

Table 6 lists the additional comments the participants gave when asked about recommended supplements.

Table 6. List of additional comments by survey participants when asked about supplements in psychiatric and psychological care.
Free text answers from psychiatrists
I refer to a dietitian
I recommend monitoring the blood sugar level
If a patient had a problem of malabsorption, bad digestion, cancer, operated bypass sleeve, etc, I recommend protein with specific check-ups and specific products and laboratory results (before I worked as a doctor in internal medicine)

*I warn my patients to be cautious for interactions when they are taking supplements together with psychopharmacological medication*

#### **Free text answers from psychologists and psychotherapists**

*I recommended to see a medical doctor when a patient asked me to recommend a supplement*

*I send my clients to see a doctor if they ask me about nutrition*

*I ask my patients to go to the doctor and check up and take some proper supplements. Or telling them to have some special fruits and vegetables to get vitamin B, iron, omega 3 ect.*

*Any discussion I have is by asking them to go to GP to discuss above*

*I recommended to see a naturopath*

*I recommended the patient to inform them about supplements*

*Do not see it as my role as a psychologist*

---

Regarding probiotics, 328 participants (31.1%) reported recommending probiotics to their patients, with no significant between profession difference ( $\chi^2$  (3, N= 1035)= 3.410,  $p$ = 0.333).

## **4. Discussion**

In this international, cross-sectional survey we investigated subjective nutritional literacy, nutritional education and the use of nutritional interventions (such as diets and supplements) in 1,056 MHPs from 52 countries. MHPs consider nutrition as an important pillar in the biopsychosocial care model. However, most of the MHPs reported having little or no nutrition literacy and no professional training in nutrition; nevertheless, nutritional approaches were being recommended by half of the MHPs, and 60% of these recommendations were for the treatment of psychiatric disorders. It appears likely that these nutritional approaches are being recommended without an adequate knowledge base.

### **4.1. Education**

The limited nutrition discussion and education from MHPs to patients may be due to an inadequate education and subsequently limited confidence in advising patients [23]. Nutritional medicine is not adequately taught in medical schools irrespective of future speciality; for example, only 40% of US medical schools reach the goal of teaching 25 hours of nutrition in preclinical years [20,21]. This education gap appears to be present worldwide. An assessment of medical nutrition education in 15 European countries and six non-European countries concluded that 'nutrition is insufficiently incorporated into medical education, regardless of country, setting, or year of medical education' [21]. This was reflected in our findings; more than two-thirds of psychiatrists and psychologists reported that they had no specific training in nutrition with only a minority (2.68% of psychologists and 2.02% of psychiatrists) who undertook mandatory courses.

We hypothesized that psychiatrists may rate their knowledge concerning nutrition significantly higher compared to the other professional groups due to their medical training. However, there was no significant difference of nutritional literacy between psychiatrists and the other professional groups. Importantly, therapists are more likely to advocate for healthy habits when they have adequate knowledge and are practicing a healthy lifestyle themselves [111]. Moreover, an American study found that 63% of psychiatric

healthcare providers practiced poor nutritional habits though they considered themselves as role models to patients [112].

Hence, in conjunction with the current literature our findings emphasize the need to implement targeted nutritional education for MHPs. Importantly, we suggest that undergraduate/graduate curriculums incorporate mandatory nutritional education as the majority of MHPs seem reluctant to participate in post-graduate training. Additionally, congresses, journal articles and interdisciplinary meetings could be feasible tools to foster interest in the field of "Nutritional Psychiatry", as these approaches were the most popular among the participants of this study.

The US Academy of Nutrition and Dietetics recommends that registered dietitians should play a significant role in the interprofessional education of medical students, residents, and physicians in practice [113]. This interprofessional approach should also be applied to the education of MHPs, the majority of which (90%) would like to expand their knowledge in 'Nutritional Psychiatry'. Based on our findings, the current practice of nutrition therapy in clinical psychiatry is untenable from an evidence-based medicine perspective with MHPs recommending questionable diets and supplements despite having little to no training in nutrition therapy.

Some psychologists answered that they would refer their patients to medical doctors (e.g. a psychologist wrote 'I send my clients to see a doctor if they ask me about nutrition'). Sending patients to see a psychiatrist or a medical doctor of another specialty may not be the best advice, as nutrition does not seem to be a mandatory subject in medical curricula in many countries. Additionally, the lack of reported referrals to nutrition specialists appears to be a gap in collaborative care and likely impeding best patient outcomes.

#### 4.2 Treatment practices

In our study, all professional groups used nutritional approaches for the treatment of psychiatric disorders despite not having education in nutritional medicine, with eating disorders and affective disorders being the most prominent indications. For somatic comorbidities, more than one third of the participants reported using nutritional interventions occasionally. This lack of education of MHPs may be the reason why dietary interventions significantly reduced depressive symptoms in a meta-analysis; however, only when delivered by accredited nutritional professionals (e.g., dietitians or nutritionists) [11].

As psychopharmacological medication can cause severe metabolic consequences, nutritional approaches could be an ideal adjunctive treatment. However, only 6.2% of the psychiatrists in our survey reported always considering the nutritional status of patients when prescribing psychopharmacological therapy and half of the participants were not aware of any regular screening for metabolic disorders in psychiatric patients in their country. This is also reflected by studies on this topic: although metabolic syndrome is common in patients taking psychopharmacological medication, hardly any patient has regular metabolic screening [114,115].

Additionally, physical health is neglected by most of the patients themselves and goes hand in hand with an increased prevalence of somatic illness such as obesity, diabetes and cardiovascular diseases followed in a significant reduction in life expectancy of 10-20 years in comparison to the general population [116]. Importantly, our survey participants rated the dietary quality of individuals with mental disorders as significantly worse when compared to the general population of their countries.

Therefore, treatment practices have to be improved to contain nutritional advice for patients complementing other recommended lifestyle interventions such as physical activity.

#### 4.3. Recommended Diets and Supplements by MHPs

Studies have revealed that certain dietary types, such as the Mediterranean diet, are associated with a lower incidence of depression [117-119] and that diet represents a major factor shaping the gut microbiome and its metabolites. Nearly half of our survey participants (43.8%) reported recommending special diets for patients with psychiatric disorders, with the Mediterranean diet being the most popular choice. A Mediterranean diet ensures an adequate nutritional intake [120], combines the beneficial effects of single nutrients, and targets a variety of mechanisms including anti-inflammatory, antioxidant, neurogenesis, and microbiome- and immune-modifying activities [121]. For example, the large European PREDIMED study demonstrated a reduced risk for incident depression in people with type 2 diabetes who were randomized to a Mediterranean diet supplemented with nuts, compared with a low-fat diet control group [122]. Conversely, a vegan diet was the least recommended diet by the survey participants. Indeed, according to a recent systematic review, vegan or vegetarian diets were found to be related to higher risks of depression but lower levels of anxiety [123]. A striking finding of our study was the remarkable number of various additional diets for mental health recommended in a free text answer field by MHPs (see Table 3). While for some diets there is evidence, others are not sufficiently researched and their potential harmful effects for patients cannot be entirely ruled out based on current evidence.

Even more participants recommended supplements instead of a special diet for patients with psychiatric disorders (58.6% vs. 43.8%). Recent study results indicate that untargeted supplementation of nutraceuticals (of both single vitamins or multi-vitamins or minerals) may not be equal to the recommendation of a properly balanced diet such as the Mediterranean diet providing food products [84,124-126]. The most recommended supplements in our survey were vitamin D, vitamin B12, and omega-3-fatty acids. While there is some evidence for supplementing these nutrients in psychiatric disorders [127-130], 164 (15.5%) participants reported recommending a range of additional supplements. Indeed, nutraceuticals seem to be widely used for the treatment of psychiatric disorders. The nutraceutical market is a quarter of the global pharmaceutical market, with growth potential in the years to come. Patients with psychiatric disorders frequently take supplements [131,132], because some 40 % of patients may not satisfactorily respond to antidepressant drugs [133] and approximately 50% of psychiatric patients prematurely discontinue their psychopharmacological treatment due to side-effects [134]. A substantial proportion of patients do not reach complete remission with state-of-the-art therapies, which reflects our incomplete understanding of the complex etiology and pathophysiology of most psychiatric disorders [135]. We assume that MHPs may recommend supplements in an effort to improve a potential unsatisfactorily treatment response of their patients or the frequent demand of patients to find a suitable, 'natural', 'complementary' or 'alternative' treatment with an estimated lower incidence of side-effects [136]. Hence, there is an urgent need to complement the current treatment paradigm with safe and sustainable interventions. Without question, micronutrients are vital to neurotransmitter synthesis, and proper functioning of the nervous and the immune system. Several micronutrients such as selenium, zinc, iron, magnesium, vitamin B12, and folic acid are found to be inversely associated with increased depression risk [7-9,137,138] and some nutraceuticals such as 5-hydroxytryptophan, omega-3 fatty acids or folic acid are used as adjunctive treatments in psychiatry [129,139,140].

However, for most supplements, the efficacy for psychiatric indications is not sufficiently researched and evidence-based recommendations are lacking for many [125]. While some supplements have been used in traditional medicine systems for thousands of years, there is a paucity of high-grade evidence for most of the supplements recommended by MHPs for the treatment of psychiatric disorders (see Table 5). Some of these supplements may have mechanisms of actions on the central nervous system as well as the gut-brain-axis yet to be discovered, and more research is necessary. Additionally, long-term effects

and side effects for most of the reported supplements are unknown. In many countries, supplements are regulated as food and not as pharmaceutical drugs which require a prescription. In our survey, psychologists reported recommending significantly more supplements than psychiatrists and psychotherapists; although the significant difference between psychologists and psychiatrists did not remain significant after correction for multiple comparisons. We suspect that psychologists may recommend supplements as an aid for therapy, because they are, in most countries by law not allowed to prescribe medication. Nevertheless, dietary supplements may contain ingredients exhibiting strong biological effects that may interact with psychopharmacological medication [141,142]. Therefore, medical and nutritional literacy is required to prevent adverse effects for patients.

#### 4.4. Strengths and Limitations

Our present study has several strengths: To the best of our knowledge, to date, this is the first and the largest study on this topic. We have a reasonably high number of participants, covering 52 countries worldwide from all income-groups. However, some countries (such as Austria) had a very high number of participants, while the response rate was significantly lower for other countries, making direct comparisons between professionals of different countries difficult. Moreover, most of our survey participants (71.9%) were female- this is not unexpected however, since MHPs are predominantly female [143,144]. In any case, there were no significant sex differences regarding the rated knowledge on "Nutritional Psychiatry" or recommendations of special diets or supplements for psychiatric disorders. Nevertheless, there could be a gender bias in the results as females may have been more interested in participating in nutrition surveys as females tend to have greater interest in healthy diet and lifestyle [145]. As its always the case in online-surveys, the rating of nutritional knowledge of the participants is based on subjective self-perception. Some participants in the group of psychiatrists and psychologists in training reported having more than 40 years of work experience which results in a mean work experience of 13.9 years. This could have been due to medical doctors who have more than one specialization (for example, one colleague stated that he first specialized in internal medicine, and then started his training in psychiatry later on in his career).

Another obvious limitation is the potential for 'selection bias', with those who have an interest in nutrition more likely to participate in such a survey. Additionally, the educational and occupational standards vary widely across the countries. Moreover, cultural established approaches may be reflected in the application of nutraceutical therapies. Given the fact that the received links were not customised, duplicate participation in the study could theoretically occur, though we feel this is unlikely to have been present to an extent that would significantly influence the results (given the time required to complete the survey and no additional benefit to the participant for completing it more than once). The survey was primarily distributed via email to national and international colleagues using a combined snowball-sampling approach. As participation of other professions than MHPs could not be ultimately ruled out due to the anonymous, self-rated nature of the survey, the questionnaire covered a question regarding current medical qualification. In case a participant reported not being a psychiatrist, psychologist or psychotherapist, these data were excluded from the survey (as listed in Figure 1, n=14 participants belonged to other professions and n=5 did not specify their profession). Lastly, the snowball-sampling technique is commonly used in websurveys like the present one. The non-probabilistic nature of the sample precludes generalizability of the results to the entire population of MHPs.

#### 4.5. Implications for future research

Future research should focus on the effectiveness and efficacy of nutrition as part of the educational curriculum for MHPs in order to sustainably integrate nutrition into the biopsychosocial treatment model and to avoid treatment errors and detrimental health effects of supplement recommendation without evidence. Most of our study participants

reported that the quality and outcome of work could be improved by further training in 'Nutritional Psychiatry' and nearly all MHPs would like to expand their nutritional literacy.

As one of the first universities in Europe, we started a training program for medical students on nutritional medicine and mental health at the Medical University of Graz, Austria in 2018. Currently, we are investigating the effects of this training program in terms of creating awareness of the topic and utilizing this knowledge into clinical practice.

## 5. Conclusions

As a first step, this international survey aimed to create awareness of an alarmingly lack of literacy concerning nutritional medicine in MHPs despite the rapidly evolving evidence base for the use of adjunctive nutritional therapies in the routine care of psychiatric patients. Improving current educational curricula and incorporating appropriate modules on nutritional psychiatry appears critical given that mental health care costs are increasing.

Subsequently patients should expect appropriate, evidence-based basic advice early in the course of treatment with the option to refer to nutrition specialists (medical doctors trained in nutritional medicine, nutritionists, dietologists, dietitians) as necessary. This collaborative process has the potential to improve outcomes related to the mental disorder and common metabolic comorbidities [146].

Most importantly, the medical maxim of 'first, do no harm' should be followed by avoiding the recommendation of supplements or diets without sufficient scientific evidence and a preceding physical examination and laboratory testing (including screening for deficiencies). The next generation of MHPs should not only be able to treat patients with state of the art psychotherapy and psychopharmacology but should also interest their patients in the care of the body and the brain, in diet, and the multifactorial cause and prevention of psychiatric disorders.
