Abstract

Cosmic inflation has presented solutions for a number of important cosmological problems, yet left some unanswered. In this paper, we present a cosmological model based on the quantization of the zero-point field which is consistent with empirical data, requires fewer assumptions, and presents answers to some of those unanswered questions. A comparison between standard cosmology and the theory presented in this paper is given below.

Vacuum energy density: Standard inflationary model needs both Hubble's constant and Matter density to estimate it. But, new cosmological model needs only Hubble's constant.

Non-vacuum energy density: Standard model can't predict it. But, the new model can predict using only Hubble's constant.

Ratio of vacuum energy to total energy: Standard model can't predict it. But, new model can predict it, that too without using Hubble's constant.

Energy conservation: In standard model, total energy is not conserved before inflation. But, in the new model, energy is conserved right from beginning of the universe whose net energy (including gravitational potential energy) is always zero.

Flatness and homogeneity: Standard model needs Inflaton field with a specific potential energy distribution to explain it. But, new model doesn't need any such hypothetical field, just the zero-point field is sufficient.

Based on the new cosmological model, in the conclusion, realistic possibility for existence of multiverse and a mechanism for end of universe are discussed.

Keywords: Cosmological constant problem, Cosmic coincidence problem, Energy conservation, Dark energy, Flatness problem, Horizon problem, Multiverse

1. Introduction

The human civilization has been curious to know the nature and evolution of the universe since ancient times. Long back, our observable universe with three spatial dimensions was thought to be infinite in extent and was considered to exist since infinite time. But, modern science has concluded that the universe has a finite extent and finite age. This is due to the following reason. If the universe was infinite and there is a finite density of stars, while looking at any direction, our view must hit a star. So, we will be surrounded by an environment whose temperature is same as that of stars. But, this is not the case. Similarly, if the universe existed since infinite time, all parts of it would have reached thermal equilibrium (or same temperature) by now by exchanging radiations. But, we do see different temperatures on different objects in the universe. So, we have now concluded that the universe has a finite extent and finite age. Consequent to discovery of General theory of Relativity by Einstein and observation of expansion of the universe by Hubble, Big-Bang model was proposed in which universe was assumed to be created by a big explosion of radiation and matter and its age was estimated to be ~ 14 billion years. However, Big-Bang model of universe suffered from five major problems viz. Cosmological constant problem, Cosmic coincidence problem, Energy conservation, Flatness and Horizon problem. At first, we will briefly explain all these problems and then proceed to develop a unified cosmological model to solve them.

Cosmological constant problem and cosmic coincidence problem:

Our universe is expanding. From the observed rate of expansion of the universe and since space is observed to be flat, solution of Einstein's field equations i.e. Friedmann's equation indicates that total energy density due to matter, radiation and vacuum must be equal to critical density $\left(\rho_{crit} = \frac{3H^2}{8\pi G}\right)$ where H is Hubble's constant. On measurement, we find that matter energy including dark matter can account only $\sim 32\%$ of this critical density. Radiation energy is found to be less than 0.1% . So, it is estimated that rest $\sim 68\%$ of the total energy of the universe must be vacuum energy (dark energy). Numerical value of this vacuum energy density comes out to be $5.3 \times 10^{-10} \text{ J/m}^3$. However, as shown by Weinberg (1989), quantum mechanically calculated vacuum energy density comes out to be $\pi^2 \hbar c / l_p^4 = 10^{114} \text{ J/m}^3$ (where l_p is Planck length) which is $\sim 10^{123}$ times more than expected astronomical value. This is known as cosmological constant problem [1-2].

Another significant problem in cosmology is the question, why is the matter energy density of the same order as the vacuum energy density today? This is surprising as in standard model, matter energy density decreases as $1/R^3$ where as vacuum energy density is assumed to be constant. This problem is known as cosmic coincidence problem [3].

Problem of conservation of energy:

Presently total matter (including dark part) in the universe is estimated to be about $\sim 10^{54}$ kg. The question is, what was the source of such a huge amount of energy? A quantum vacuum fluctuation can at best create Planck energy of ~ 0.02 mg in a Planck time of $\sim 5.4 \times 10^{-44}$ sec. To answer this question, it was proposed that sum total of energy of the universe due to matter/vacuum and gravitation potential energy might be zero so that the law of conservation of energy of the universe is satisfied. This is possible as the sign of gravitational potential energy is negative whereas that of other forms is positive. To make net energy zero, magnitude of gravitational potential energy must be equal to the magnitude of non-gravitational part (matter plus vacuum). But, mathematical proof of zero-energy universe needs the flatness of space as an assumption [4] i.e. zero-energy universe is a consequence of flatness. Since the space became flat only after inflation, the question remains about the source of energy before and during inflation. But, in this paper, we will prove zero-energy universe without using flatness of space and show that flatness is actually consequence of zero net energy density.

It is important to note that the energy-momentum tensor in Einstein's field equation contains only the matter/radiation terms, not the gravitational potential energy. This doesn't mean, gravitational potential energy doesn't exist. It just means, in Einstein's theory of gravity, we deal with curvature of space-time to calculate the dynamics of material bodies. *Role of gravitational potential energy has been taken over by curvature of space-time.* That's why we generally state that covariant divergence of energy-momentum tensor is zero not the "ordinary divergence". Covariant divergence includes a term related to curvature.

Some authors have argued, in an expanding space-time, Einstein's field equation doesn't imply conservation of energy due to matter and radiation [5]. This appears so because Einstein's theory of gravity is a geometric theory and it considers only matter and radiation in its energy-momentum tensor, not the gravitational potential energy. However, as the law of conservation of energy has never been violated in any experiment so far, a cosmological model that satisfies the law of conservation of energy will be scientifically more satisfying.

Flatness and Horizon problems and inflationary solution:

Infinitesimal length of a line element in our space-time is given by the generalized Friedmann-Robertson-Walker (FRW) metric,

$$d\sigma^2 = -c^2 dt^2 + R^2 \left[\frac{dr^2}{1-kr^2} + r^2 d\theta^2 + r^2 \sin^2 \theta d\phi^2 \right] \quad (1)$$

Where ‘ R ’ is scale factor (or radius of curvature), k is *observed* curvature constant which can be +1 for positive curvature, 0 for flat space or -1 for negative curvature. Note that k can take any value (+1, 0 or -1) depending upon the total energy density and rate of expansion of the universe even if the universe is physically closed (like an observer freely falling in a gravitational field cannot detect the curvature of space-time). Thus, in addition to energy-momentum tensor, dynamics of the observer plays a very important role in the curvature measured by him. Friedmann’s solution of Einstein’s field equation is given by [6-7],

$$\left(\frac{\dot{R}}{R} \right)^2 = \frac{8\pi G}{3} \rho - \frac{k}{R^2} c^2 \quad (2)$$

$$\frac{\ddot{R}}{R} = -\frac{4\pi G}{3} \left(\rho + 3 \frac{p}{c^2} \right) \quad (3)$$

Critical density is defined by the dynamical properties of the universe is, $\rho_{crit} = \frac{3H^2}{8\pi G}$ where

$H = \frac{\dot{R}}{R}$ (Hubble’s constant). Energy density is expressed in terms of this critical density as

Ω -parameter defined by, $\Omega = \frac{\rho}{\rho_{crit}}$. Thus, in terms of above definitions, Eq. (2) becomes,

$$(\Omega^{-1} - 1) \rho R^2 = \frac{-3kc^2}{8\pi G} \quad (4)$$

Only if Ω is exactly equal to 1, then $k = 0$. If $\Omega > 1$, $k = +1$. If $\Omega < 1$, $k = -1$.

As in a matter dominated universe, ρ varies as R^{-3} , Eq. (4) indicates that deviation of Ω from 1 is expected to increase in direct proportion to R . This instability of Ω near the value of ~ 1 is known as *Flatness problem*. To be specific, presently Ω is found to be close to 1 with an accuracy of better than 0.5%. As R has increased by a factor of $\sim 10^{61}$ (from Planck size $\sim 10^{-35}$ m to current size $\sim 10^{26}$ m), Ω must be close to 1 in the initial time with an accuracy of better than 10^{-62} %. Thus, flatness problem seeks an answer for such a precise fine tuning of Ω at the initial stage of the universe.

Horizon problem poses a challenge to explain the extraordinary homogeneity observed in temperature of causally disconnected regions of the universe despite of the finite speed of light. With expansion of the universe, temperature of the universe decreased and at about $\sim 380,000$ years, temperature was sufficiently low for recombination of electrons and protons and thus neutral atoms were formed. As neutral atoms have very low cross section for scattering of photons as compared to charged particles, photons decoupled from the plasma and have been streaming through the universe since that time. Of course, due to expansion of the universe, their wavelengths have been stretched and these photons are known as Cosmic Microwave Background (CMB) radiation. When we measure the spectrum of this CMB radiation, it very well fits to a black body spectrum of temperature of ~ 2.726 K. Even if we compare the temperatures of two opposite regions of the sky by their CMB radiation spectrum, both the temperatures agree with each other within an accuracy of ~ 0.001 K. The fact that we are measuring ‘now’ indicates, the two opposite regions have just come in causal contact with us. So, they must not have been in causal contact with each other as radiation from one part has covered only half the distance from other part. In fact, following the method of [8], it can be shown that the observable universe consists of about 36000 causally disconnected patches which surprisingly have almost same temperatures. This is as follows. If the present radius of the universe in form of 3-sphere is R_0 , the co-moving particle horizon at any time t is given by,

$$S(t) = R_0 \int_0^t \frac{cdt}{R} \quad (5)$$

Taking $R=At^\alpha$ (for matter dominated universe $\alpha=2/3$ and for radiation dominated $\alpha=1/2$),

$$S(t) = R_0 \int_0^t \frac{cdt}{At^\alpha} = \frac{R_0 ct^{1-\alpha}}{A(1-\alpha)} \quad (\text{for } \alpha \neq 1)$$

If t is the time when photon decoupling occurred releasing the CMB radiation and t_0 is present time, the ratio of co-moving horizon volume today to the co-moving horizon volume at photon decoupling is,

$$\left[\frac{S(t_0)}{S(t)} \right]^3 = \left(\frac{t_0}{t} \right)^{3-3\alpha}$$

Or

$$\left[\frac{S(t_0)}{S(t)} \right]^3 = \left(\frac{R_0}{R} \right)^{\frac{3}{\alpha}-3} = (1+z)^{\frac{3}{\alpha}-3} \quad (6)$$

Where z =Red shift of CMB radiation.

Taking $z=1100$ and $\alpha=2/3$ for matter dominated universe,

$$\left[\frac{S(t_0)}{S(t)} \right]^3 = 36482$$

Thus, presently observable universe contains about ~ 36000 causally disconnected patches. Still, they have almost same temperature of $\sim 2.726 \pm 0.001$ K. This is known as *Horizon problem*.

In order to explain the Flatness and Horizon problems, Alan Guth [9-10] and others have proposed the cosmic inflation theory which assumes the existence of an inflaton field having a large potential energy in the early universe. Its negative pressure caused exponential expansion of the universe from $\sim 10^{-30}$ m to $\sim 10^{-2}$ m during a period from about $\sim 10^{-35}$ s to $\sim 10^{-32}$ s after creation of the universe. Since the energy density of the inflaton field is assumed to be nearly constant during this expansion, Eq. (4) indicates that whatever initial value Ω starts with, it approaches 1 with increasing radius R (as deviation from 1 is proportional to R^{-2}). Thus, instability of Ω is avoided during early stage of universe. After $\sim 10^{-32}$ s even if inflation stops, Ω is already so close to 1 that it will take very long to deviate from 1. This is how inflation theory explains the avoidance of instability of Ω in early universe and why the value of Ω is ~ 1 . Similarly, as the universe expanded by a huge factor of $\sim 10^{28}$ in a very small time interval of $\sim 10^{-32}$ s, outer portion of every causal patch was pushed out of the horizon. After inflation stopped and as horizon still expands at the speed of light, we are seeing those parts which were originally in causal contact with us before inflation. Thus, horizon problem is solved in cosmic inflation theory.

But, the limitation of the inflation theory is that it cannot explain the present rate of expansion of the universe by predicting the value of vacuum energy density and it also can't predict matter energy density. Since the space became flat only after inflation, inflationary model can't prove the net energy of universe to be zero before inflation and thus the law of energy conservation is violated during pre-inflation period. In addition, the magnitude and variation of the potential energy with strength of the inflaton field are artificially decided to make it fit to explain the flatness and horizon problems. That's why currently there are so many inflationary models proposed in literature. Mechanism of graceful exit from inflationary stage also casts some doubt on the theory. Recently due to this, Paul J. Steinhardt, one of the architects of the theory, has turned against it [11-12].

Our approach:

To solve the above-mentioned problems, we will develop a unified cosmological model in a rigorous manner which will quantitatively show how creation of universe doesn't violate the law of conservation of energy and how our model simultaneously solves the cosmological constant problem, cosmic coincidence problem, flatness problem and horizon problem of the universe. The structure of the paper is as follows. In the next section, we describe our cosmological model that leads to expression for vacuum and matter energy density and solves cosmic coincidence problem. Using these expressions, in the next three sections, we demonstrate working of the law of conservation of energy and solve the cosmological constant, flatness and horizon problems in our model. In the conclusion, we compare the advantages and predictive power of our cosmological model with that of the standard model. Finally, in the light of our model, we discuss possibility of existence of multiverse.

2. Development of generalized cosmological model and solution of cosmic coincidence problem

In standard cosmology, universe is assumed to be isotropic and homogeneous. To impose the condition of isotropy, Einstein visualized the universe as a closed hyper-surface (surface of a 3-sphere) existing in a 4-dimensional space. This exciting idea of Einstein as expressed in his original paper [13] is quoted below.

“We arrive at such a space, for example, in the following way. We start from a Euclidean space of four dimensions, $\xi_1, \xi_2, \xi_3, \xi_4$, with a linear element $d\sigma$; let therefore, $d\sigma^2 = d\xi_1^2 + d\xi_2^2 + d\xi_3^2 + d\xi_4^2$

In this space we consider the hyper-surface, $R^2 = \xi_1^2 + \xi_2^2 + \xi_3^2 + \xi_4^2$

Where R denotes a constant. The points of this hyper-surface form a three-dimensional continuum, a spherical space of radius of curvature R .”

To maintain isotropy of space, we will follow the Einstein's model of universe that lies on the surface of a 3-sphere (hyper-sphere) existing in a four-dimensional space. As described in section-1, curvature constant k in FRW metric of this space represents the *observed* characteristics of a line element depending upon energy density and Hubble's constant. So, even if globally the universe is closed and finite, k may be +1, 0 or -1 depending upon the rate of expansion of universe (just like space-time looks flat to an observer freely falling under a gravitational field). As per quantum field theory, this space in the form of hyper-

surface of 3-sphere must have the zero-point energy and sum of energies for all possible modes of oscillations is the vacuum energy. We will assume a common zero-point scalar field that is responsible for energy of all the fundamental particles. Number of particles having same energy increases when a particular zero-point mode is excited. Properties of particles other than energy appear when excited field couples with other fields such as Higg's field, electromagnetic field etc. So, particles of same energy even if have different rest mass, charge or spin correspond to a single and common mode of zero-point wave.

Since the space of our universe is closed and spherically symmetric, circumference must be integer multiple of wavelength of zero-point wave. Mathematically,

$$2\pi R = n\lambda \quad (7)$$

Where R is the radius of universe in the form of 3-sphere, λ is wavelength of zero-point field, n is an integer varying from 1 to n_{\max} and n_{\max} is decided by lowest possible wavelength λ_{\min} .

Minimum wave length must be of the *order* of Planck length $l_p = \sqrt{\frac{\hbar G}{c^3}} = 1.6 \times 10^{-35} m$, as distances smaller than Planck length cannot be defined [14-15]. We will take the cutoff wavelength as $\lambda_{\min} = \beta l_p$ where β is a constant *nearly* equal to 1. Using this λ_{\min} in Eq. (7) we get,

$$n_{\max} = \frac{2\pi R}{\lambda_{\min}} = \frac{2\pi R}{\beta l_p} \quad (8)$$

Initial radius R_i of universe can be found from Eq. (8) by putting n_{\max} equal to 1 and it is given by,

$$R_i = \frac{\beta l_p}{2\pi}.$$

Let us now consider the example of Bohr's hydrogen atom. An electron while revolving around the nucleus remains as a standing wave and we only quantize the wavelength or magnitude of momentum. The direction of momentum of the electron in Bohr's theory remains in a state of superposition of all possible directions on surface of 2-sphere due to spherical symmetry. We don't consider a separate state corresponding to each possible direction of momentum. Similarly, for the standing zero-point scalar wave on the surface of hyper-sphere of universe, direction of momentum can remain in a state of superposition of all possible directions due to symmetry. Zero-point scalar field can continue to exist in a superposition state as it is unable to interact with anything else. That's why, in contrast to conventional method, we will consider only the modes with distinct *magnitudes* of

momentum. *Different directions of momentum cannot lead to new modes as each zero-point scalar wave propagates simultaneously in a quantum superposition state along all directions in 3-D space.* So, total vacuum energy of the universe considering all modes of zero-point oscillations of different magnitudes of momentum is given by,

$$U_{vac} = \sum \frac{1}{2} h \nu = \frac{hc}{2} \sum \frac{1}{\lambda}$$

Using Eq. (7),

$$U_{vac} = \frac{hc}{4\pi R} \sum_1^{n_{max}} n = \frac{\hbar c}{4R} n_{max}^2 \left(1 + \frac{1}{n_{max}} \right) \quad (9)$$

Putting the value of n_{max} from Eq. (8) and $l_p = \sqrt{\frac{\hbar G}{c^3}}$ in above expression, total vacuum energy becomes,

$$U_{vac} = \frac{\pi^2 c^4 R}{\beta^2 G} \left(1 + \frac{\beta l_p}{2\pi R} \right) \quad (10)$$

Dividing the above by the surface volume of hyper-sphere $2\pi^2 R^3$, vacuum energy density is,

$$u_{vac} = \frac{c^4}{2\beta^2 G R^2} \left(1 + \frac{R_i}{R} \right) \quad (11)$$

As $R \gg R_i$, second term in (10) and (11) is negligible and so, vacuum energy and its density are given by,

$$U_{vac} = \frac{\pi^2 c^4 R}{\beta^2 G} \quad (12)$$

$$u_{vac} = \rho_{vac} c^2 = \frac{c^4}{2\beta^2 G R^2} \quad (13)$$

Numerical value of vacuum energy density u_{vac} will be calculated in section-4 after we derive the analytical expression for R .

Now, Let us calculate the average energy density due to non-vacuum components (ordinary matter, dark matter and radiation) of the universe. If ϕ is scalar field of the zero-point oscillation, energy density and pressure are given by [16],

$$u_{vac} = \frac{1}{2} \left(\frac{\partial \phi}{c \partial t} \right)^2 + \frac{1}{2} \left[\left(\frac{\partial \phi}{\partial x} \right)^2 + \left(\frac{\partial \phi}{\partial y} \right)^2 + \left(\frac{\partial \phi}{\partial z} \right)^2 \right] + V(\phi) \quad (14)$$

$$p = \frac{1}{2} \left(\frac{\partial \phi}{c \partial t} \right)^2 - \frac{1}{6} \left[\left(\frac{\partial \phi}{\partial x} \right)^2 + \left(\frac{\partial \phi}{\partial y} \right)^2 + \left(\frac{\partial \phi}{\partial z} \right)^2 \right] - V(\phi) \quad (15)$$

Just like in a harmonic oscillator, energy will be shared equally between potential energy (depending on ϕ) and kinetic energy (depending on derivatives of ϕ). So,

$$\frac{1}{2} \left(\frac{\partial \phi}{\partial t} \right)^2 + \frac{1}{2} \left[\left(\frac{\partial \phi}{\partial x} \right)^2 + \left(\frac{\partial \phi}{\partial y} \right)^2 + \left(\frac{\partial \phi}{\partial z} \right)^2 \right] = V(\phi) \quad (16)$$

Due to relativistic consideration, giving equal status to time and space coordinates, each term in LHS of Eq. (16) becomes equal. So,

$$\frac{1}{2} \left(\frac{\partial \phi}{\partial t} \right)^2 = \frac{1}{2} \left(\frac{\partial \phi}{\partial x} \right)^2 = \frac{1}{2} \left(\frac{\partial \phi}{\partial y} \right)^2 = \frac{1}{2} \left(\frac{\partial \phi}{\partial z} \right)^2 = \frac{V(\phi)}{4} \quad (17)$$

Using Eq. (16) and (17) in Eq. (14) and (15), we get,

$$\begin{aligned} u_{vac} &= 2V(\phi) \quad , \quad p = -V(\phi) \\ \Rightarrow p &= -\frac{u_{vac}}{2} \end{aligned} \quad (18)$$

Expanding the bracket in Eq. (10) and then taking differential,

$$dU_{vac} = \frac{\pi^2 c^4}{\beta^2 G} dR \quad (19)$$

In a matter dominated universe, pressure is mainly caused by vacuum energy (gravitational potential energy and its pressure are not considered in Einstein field equation as it is a geometric theory and pressure due to radiation is neglected as radiation energy is less than $\sim 0.1\%$). Since Einstein's field equation makes the covariant derivative of energy-momentum tensor zero ($T_{;\nu}^{\mu\nu} = 0$), energy conservation equation as derived by Weinberg [17] is,

$$\begin{aligned} d(uR^3) + p(3R^2 dR) &= 0 \\ \Rightarrow dU_{nonvac} + dU_{vac} + p dV &= 0 \end{aligned} \quad (20)$$

(As surface volume of hyper-sphere $V = 2\pi^2 R^3$)

Using Eq. (19), (18) and (11) in Eq. (20), we get,

$$\begin{aligned} dU_{nonvac} &= -\frac{\pi^2 c^4}{\beta^2 G} dR + \frac{3\pi^2 c^4}{2\beta^2 G} \left(1 + \frac{R_i}{R} \right) dR \\ \text{Or} \quad dU_{nonvac} &= \frac{\pi^2 c^4}{2\beta^2 G} \left(1 + 3\frac{R_i}{R} \right) dR \end{aligned} \quad (21)$$

Thus, we find that non-vacuum energy of the universe also increases with radius of the universe. Increase of non-vacuum energy happens by way of excitation of zero-point oscillators (i.e. creation of matter and radiation). We will prove in next section that the energy

required for increase of both vacuum and non-vacuum parts comes from gravitational potential energy which becomes more and more negative and keeps the net energy of universe zero.

Integrating Eq. (21) from R_i to R , we get,

$$U_{nonvac} = \frac{\pi^2 c^4 R}{2\beta^2 G} \left[1 - \frac{R_i}{R} + \frac{3R_i}{R} \ln\left(\frac{R}{R_i}\right) \right] \quad (22)$$

Dividing Eq. (22) by surface volume ($2\pi^2 R^3$) of hyper-sphere, we get of non-vacuum energy density,

$$u_{nonvac} = \frac{c^4}{4\beta^2 GR^2} \left[1 - \frac{R_i}{R} + \frac{3R_i}{R} \ln\left(\frac{R}{R_i}\right) \right] \quad (23)$$

$$\text{For } R \gg R_i, \quad U_{nonvac} = \frac{\pi^2 c^4 R}{2\beta^2 G} \quad (24)$$

$$u_{nonvac} = \rho_{nonvac} c^2 = \frac{c^4}{4\beta^2 GR^2} \quad (25)$$

If $R \gg 10^{-35}\text{m}$, comparing Eq. (13) and (25), we find that the ratio of non-vacuum energy density to the vacuum energy density is 1/2 and so, ratio of vacuum energy to total energy is 2/3. It is independent of radius R of universe and *in fact independent of all constants of the universe*. In other words, theoretically, ~ 66.7% of total energy should be in the form of dark energy and rest 33.3% should be in the form of non-vacuum component i.e. matter, dark matter and radiation since the beginning of universe. Thus, the cosmic coincidence problem which questions why the matter energy density is of the same order as vacuum energy density is explained.

3. Conservation of energy in an expanding universe

Using Eq. (13) and (25), total mass density due to vacuum and non-vacuum energy is given by,

$$\rho = \rho_{vac} + \rho_{nonvac} = \frac{3c^2}{4\beta^2 GR^2} \quad (26)$$

Putting the above value $\rho = \frac{3c^2}{4\beta^2 GR^2}$ and $p = -\frac{u_{vac}}{2} = \frac{-c^2}{4\beta^2 GR^2}$ from Eq. (18) and Eq. (13)

in Fiedmann's Equations (2) and (3), we get,

$$\left(\frac{\dot{R}}{R}\right)^2 = \frac{8\pi G}{3} \left(\frac{3c^2}{4\beta^2 GR^2}\right) - \frac{k}{R^2} c^2$$

$$\frac{\ddot{R}}{R} = -\frac{4\pi G}{3} \left(\frac{3c^2}{4\beta^2 GR^2} - 3\frac{c^2}{4\beta^2 GR^2}\right) = 0$$

Simplifying,

$$\dot{R} = c \sqrt{\frac{2\pi}{\beta^2} - k} \quad (27)$$

$$\text{And} \quad \ddot{R} = 0 \quad (28)$$

Thus, we find that the radius of universe increases with time at a uniform rate of

$\dot{R} = \gamma c$, where $\gamma = \sqrt{\frac{2\pi}{\beta^2} - k}$. So, at any instant of time τ , radius of universe is, $R = R_i + \gamma c \tau$.

After few time steps of Planck time ($\sim 10^{-44}$ s), $R_i \ll \gamma c \tau$ so that we can write, $R = \gamma c \tau$.

For calculation of gravitational potential energy of any small mass m due another larger Mass M , we should use the general relativistic expression given by Voracek [18],

$$P.E. = mc^2 \left[\left(1 - \frac{2GM}{c^2 r} \right)^{1/2} - 1 \right]. \text{ However, as the Schwarzschild radius is very much small}$$

as compared to interstellar/ intergalactic distances i.e. $\frac{2GM}{c^2} \ll r$, above expression reduces

to,

$$P.E. = mc^2 \left[\left(1 - \frac{1}{2} \frac{2GM}{c^2 r} \right) - 1 \right] = -\frac{GMm}{r}, \text{ which is Newton's law.}$$

So, we can safely use Newton's law for calculating gravitational potential energy. However, since gravitational effect is transmitted at the speed of light, we will use the retarded form of Newton's expression for gravitational potential energy and also consider time dependence of energy density of the universe. As shown in Fig. 1, mass at a specific time τ contained in thin strip on the surface of hyper-sphere at angular distance of ϕ from a unit mass can contribute to the gravitational potential energy at any time t and distance to be used in Newton's expression must be $c(t-\tau)$.

Fig. 1 Gravitational potential energy due to a thin strip equidistant from a unit mass

So, gravitational potential energy ($P.E.$) of the unit mass is,

$$P.E. = - \int_0^{\phi_{\max}} G \frac{\rho(\tau) 4\pi [R(\tau)]^3 \sin^2 \phi d\phi}{c(t-\tau)} \quad (29)$$

Another condition is that the ϕ must be equal to the angular distance covered by the gravitational radiation during the time interval from τ to t . Mathematically,

$$\phi = \int_{\tau}^t \frac{cd\tau'}{R} = \int_{\tau}^t \frac{cd\tau'}{\gamma c\tau'} = \frac{1}{\gamma} \ln\left(\frac{t}{\tau}\right)$$

$$\Rightarrow t = \tau e^{\phi\gamma} \quad (30)$$

From Eq. (30), maximum limit of ϕ is, $\phi_{\max} = \infty$ (when $\tau=0$). Using the value of total mass density ρ from Eq. (26) and value of t from Eq. (30), Eq. (29) becomes,

$$P.E. = - \frac{3\pi c}{\beta^2} \int_0^{\infty} \frac{R \sin^2 \phi d\phi}{\tau(e^{\phi\gamma} - 1)}$$

As $R(\tau) = \gamma c\tau$, we get,

$$P.E. = - \frac{3\pi^2 \gamma}{\beta^2} \int_0^{\infty} \frac{\sin^2 \phi d\phi}{(e^{\phi\gamma} - 1)}$$

$$\text{As } \gamma = \sqrt{\frac{2\pi}{\beta^2} - k},$$

$$P.E. = -\frac{3c^2\gamma(\gamma^2 + k)}{2} \int_0^\infty \frac{\sin^2 \phi d\phi}{(e^{\phi\gamma} - 1)} \quad (31)$$

Total gravitational energy due to all the matter/vacuum of energy $U_{matt+vac}$ is given by,

$$U_{grav} = \frac{1}{2}(P.E.) \times \frac{U_{matt+vac}}{c^2}$$

(Note factor 1/2 is here to avoid double counting of interaction energy between two particles)

Using Eq. (31) in above,

$$\frac{U_{grav}}{U_{matt+vac}} = -\frac{3\gamma(\gamma^2 + k)}{4} \int_0^\infty \frac{\sin^2 \phi d\phi}{(e^{\phi\gamma} - 1)} \quad (32)$$

Evaluating above expression, we find that it can be equal to -1 (or $U_{grav} = -U_{matt+vac}$) only if $\gamma=2$ (for $k=0$), $\gamma=1.12$ (for $k=+1$) and $\gamma=2.5$ (for $k=-1$). Thus, whatever be the value of k , it is possible to have total energy of the universe, $U_{Total} = U_{matt+vac} + U_{grav} = 0$ (Irrespective of the radius of universe). So, law of conservation of energy is not violated during the process of creation of the universe. It will be proved in next section that $k=0$ ($\gamma=2$) is the only possible value from general relativistic consideration.

4. Solution of Flatness problem and Cosmological constant problem

We first restate the Eq. (4) i.e. Friedmann's first equation in terms of Ω ,

$$(\Omega^{-1} - 1)\rho R^2 = \frac{-3kc^2}{8\pi G}$$

Putting the value $\rho = \frac{3c^2}{4\beta^2 GR^2}$ from Eq. (26), we get

$$(\Omega^{-1} - 1) = \frac{-k\beta^2}{2\pi} \quad (33)$$

Thus, as deviation of Ω from 1 remains constant irrespective of the radius of the universe, the instability of Ω (which is main concern for flatness problem) is eliminated. However, as Ω is a constant as per Eq. (33), for three possible values of $k = +1, 0$ and -1 , there are three possible values of Ω . We will now predict the expected value of Ω which will be proved to be equal to 1.

In the previous section, we have proved that law of energy conservation can be satisfied for specific pairs of values of γ and k . When it happens, gravitational potential

energy density u_{grav} becomes equal and opposite of the average non-gravitational energy density $u_{matt+vac}$ (matter plus vacuum). So, net energy density, $u_{grav} + u_{matt+vac} = 0$. Since gravitational field moves at the speed of light, its pressure is given by, $p_{grav} = \frac{1}{3}|u_{grav}|$ (modulus is taken as pressure due to gravitational radiation is positive). As described in section 2, out of the non-gravitational part, pressure is caused by vacuum energy and it is negative given by, $p = -\frac{u_{vac}}{2}$ and $u_{vac} = \frac{2}{3}u_{matt+vac}$. So, $p = -\frac{u_{matt+vac}}{3}$. So net pressure is given by, $p_{net} = p_{grav} + p = \frac{1}{3}|u_{grav}| - \frac{u_{matt+vac}}{3} = 0$ (as magnitudes of u_{grav} and $u_{matt+vac}$ are equal). Thus, total energy density and total pressure become zero all over the universe.

Now, let us write the linearized form of Einstein field equation as derived by Weinberg [17],

$$R_{\mu\nu}^{(1)} - \frac{1}{2}\eta_{\mu\nu}R_{\lambda}^{(1)\lambda} = \frac{8\pi G}{c^4}[T_{\mu\nu} + t_{\mu\nu}] \quad (34)$$

Second term in right hand side of above equation represents the contribution due to gravitational field in the total energy-momentum tensor. In our case, we have seen that contributions of gravitational field make both total energy density and pressure equal to zero. Thus, as the right hand side of Eq. (34) i.e. total energy-momentum pseudo-tensor becomes zero all over the space of the universe, curvature of space-time also becomes zero i.e. $k = 0$.

Using $k = 0$ in Eq. (33), $\Omega=1$ or space is always flat.

Putting $k=0$ in $\gamma = \sqrt{\frac{2\pi}{\beta^2} - k}$, we get,

$$\gamma = \frac{\sqrt{2\pi}}{\beta} \quad (35)$$

Since Hubble's constant is $H = \frac{\dot{R}}{R}$,

Radius of universe is, $R = \frac{\dot{R}}{H} = \frac{\gamma c}{H} = \frac{\sqrt{2\pi} c}{\beta H}$

Putting the above expression of R in Eq. (13) and (25), vacuum energy density and nonvacuum energy density become,

$$u_{vac} = \frac{c^2 H^2}{4\pi G} \quad (36)$$

$$u_{nonvac} = \frac{c^2 H^2}{8\pi G} \quad (37)$$

Note that, in contrast to standard cosmology, vacuum energy density here needs only the Hubble's constant and doesn't need matter density for its calculation. The value of u_{vac} calculated from Eq. (36) is $\sim 5.2 \times 10^{-10} \text{ J/m}^3$ (taking $H=67.9 \text{ km/s Mpc}^{-1}$) and it agrees well with the value estimated using standard cosmological model and observed data of Planck Collaboration [19]. The earlier difference by a factor of $\sim 10^{123}$ between quantum mechanical calculation and cosmological observation of vacuum energy is eliminated and cosmological constant problem is solved. Non-vacuum energy density u_{nonvac} (which standard cosmology can't predict) can be estimated from Eq. (37) and it is found to be $\sim 2.6 \times 10^{-10} \text{ J/m}^3$. It matches well with the observed data of Planck Collaboration [19].

Finally, using the conclusion of previous section i.e. $\gamma = 2$ (corresponding to $k=0$) for energy conservation, rate of expansion of universe is, $\dot{R} = \gamma c = 2c$. As $\gamma = \sqrt{2\pi} / \beta$, $\beta=1.25$. So, minimum possible wavelength of a zero-point wave is 1.25 times the Planck length. Initial radius R_i of universe is given by, $R_i = \frac{\beta l_p}{2\pi} = 3.2 \times 10^{-36} \text{ m}$. Because universe expands at a uniform rate of $\dot{R} = 2c$, age of universe is, $t_0 = R_0 / \dot{R} = 1/H_0 = 14.4$ billion years. As angular distance of any galaxy from us on the surface of 3-sphere remains constant during expansion of the universe, if its distance from us is x , $\dot{x}/x = \dot{R}/R \Rightarrow \dot{x} = Hx$ (Hubble's law). At present time, Hubble's constant ($H_0 = 1/t_0$) remains nearly constant during our period of measurement. So, acceleration of any galaxy from us is $\ddot{x} = H_0 \dot{x} = H_0^2 x \neq 0$ even though $\ddot{R} = 0$ as per Eq. (28). Physically, a star appears accelerating from us because farther it goes, more space is there in between to expand.

5. Solution of Horizon problem:

As the rate of expansion of universe is constant i.e. $\dot{R} = 2c$, we can write, $R = R_i + 2ct$ (neglecting nonlinear part during the time comparable to Planck time $\sim 10^{-44} \text{ s}$). So, for $R \gg R_i$, $\alpha=1$. If we put $\alpha \rightarrow 1$ in Eq. (6), number of causally disconnected patches comes out to be 1 (not 36000) and horizon problem is solved. However, we will not directly use eq. (6) as it assumes $R = At^\alpha$ and $\alpha \neq 1$. So, putting $R = R_i + 2ct$ in Eq. (5), co-moving particle horizon at any time t is given by,

$$S(t) = R_0 \int_0^t \frac{cdt}{R_i + 2ct} = \frac{R_0}{2} \ln \left[1 + \frac{2ct}{R_i} \right]$$

Then, the ratio of co-moving horizon volume at present time t_0 to the co-moving horizon volume at the time t_{CMB} of photon decoupling is,

$$\left[\frac{S(t_0)}{S(t_{CMB})} \right]^3 = \left(\ln \left[1 + \frac{2ct_0}{R_i} \right] / \ln \left[1 + \frac{2ct_{CMB}}{R_i} \right] \right)^3$$

Putting $R_i = 3.2 \times 10^{-36} m$, $t_0 = 14.4 \text{ by}$ and $t_{CMB} = 380000 \text{ y}$,

$$\left[\frac{S(t_0)}{S(t_{CMB})} \right]^3 = 1.24$$

Thus, we find that, in contrast to standard cosmology, the whole observable universe is nearly causally connected and it doesn't contain ~ 36000 causally disconnected patches.

We will also give here an alternative calculation which will show that the co-moving size of patch from which CMB photons come to us is much smaller than the co-moving particle distance at the time of release of CMB radiation. After the release of CMB radiation, the photons we are detecting now must have moved through an angular distance of,

$$\begin{aligned} \theta &= \int_{t_{CMB}}^{t_0} \frac{cdt}{R} = \int_{t_{CMB}}^{t_0} \frac{cdt}{R_i + 2ct} \\ \theta &= \frac{1}{2} \ln \left(\frac{R_i + 2ct_0}{R_i + 2ct_{CMB}} \right) \end{aligned} \quad (38)$$

Putting $t_0 = 14.4 \text{ by}$ and $t_{CMB} = 380,000 \text{ y}$, $\theta = 5.27$ radian. Since, this is more than π , as shown Fig. 2, minimum angular distance between two opposite points A and B of our present horizon is, $\varphi = 2(2\pi - \theta) = 2.03 \text{ rad}$.

Theoretically maximum angular distance a photon can move till the time of photon decoupling is,

$$\psi = \int_0^{t_{CMB}} \frac{cdt}{R} = \int_0^{t_{CMB}} \frac{cdt}{R_i + 2ct} = \frac{1}{2} \ln \left[1 + \frac{2ct_{CMB}}{R_i} \right] \quad (39)$$

Putting $t_{CMB} = 380,000 \text{ yr}$ and $R_i = 3.2 \times 10^{-36} m$,

$$\psi = 66 \text{ radian}$$

Thus, as $\frac{\psi}{\varphi} = 33$ i.e. maximum angular distance that a photon can move till CMB release is about ~ 33 times more than the angular distance between two opposite points of horizon, it is possible for our horizon to attain thermal equilibrium and achieve nearly same temperature. Thus, our cosmic model solves the horizon problem.

Fig.2 Angular distance between two opposite points A and B on our horizon located on the hyper-surface of 3-sphere

6. Conclusion

In this paper, we have developed a unified cosmological model to solve five important astrophysical problems viz. cosmological constant problem, cosmic coincidence problem, energy conservation, flatness and horizon problem. Our model predicts the density of vacuum energy taking only Hubble's constant as input whereas standard cosmology needs both Hubble's constant and matter density to estimate. We have also developed mathematical expression for energy density of non-vacuum component (matter plus radiation) matching with observational data which standard cosmology can't predict. Ratio of vacuum energy to total energy in our model is a constant i.e. $2/3$ irrespective of the Hubble's constant. In contrast to standard inflationary model, our theory doesn't need flatness of space as a pre-requirement to prove zero-energy universe or to save law of conservation of energy. In our model, flatness of space is a consequence of zero-energy universe. So, in our model, energy is conserved right from the beginning of universe since it is always zero whereas in standard model it is so only after inflation period. We have found that total vacuum and non-vacuum energy increases with expansion of the universe and it comes from gravitational potential energy which becomes more and more negative. In contrast to standard cosmology, our model doesn't have to invoke any inflaton field having a specific potential energy distribution to prove flatness and homogeneity of horizon. It just uses quantized zero-point scalar field in a closed universe.

Highlights of the advantages and predictive power of our cosmological model as compared to standard model are given in Table. 1.

Table. 1 A comparison of our new cosmological model with standard model

Variables to be determined	<i>Standard inflationary cosmology</i>	<i>New cosmological model</i>
<i>Vacuum energy density</i>	To predict, needs both Hubble's constant and Matter density	To predict, needs only Hubble's constant
<i>Non-vacuum energy density</i>	Cannot predict	Can predict, needs only Hubble's constant
<i>Ratio of vacuum energy to total energy</i>	Needs Hubble's constant and Matter density	No input required. Ratio=2/3=66.7%
<i>Is energy conserved before inflation?</i>	No	Yes
<i>To explain Flatness of space</i>	Needs Inflaton field with a specific potential energy distribution	Flatness is a consequence of energy conservation
<i>To explain homogeneity of Horizon</i>	Needs Inflaton field with a specific potential energy distribution	Needs only Zero-point field

An interesting prediction of our cosmological model is that radius of the universe (in the form of 3-sphere) increases at the rate of double the speed of light ($\gamma = 2$). This doesn't violate special theory of relativity as it is the speed of 3-D space in infinite 4-D space whereas special relativity limits the velocity of particles in 3-D space to speed of light. We have also found that minimum possible wavelength of a zero-point wave is 1.25 times the Planck length.

As in our model, a miniscule bubble of empty space of the size of Planck length created by quantum fluctuation can grow into a mature universe (without need of energy from outside), there is no reason why there can't be numerous universes in different stages of their life in the four-dimensional infinite space. So, our theory supports the idea of multiverse. Many universes must have been created earlier and many will be created in future. Since the vacuum (or dark) energy density reduces as $1/R^2$, if there exists a minimum allowable vacuum energy density, instantaneous annihilation of our universe after a finite time is possible without violating energy conservation as net energy of the universe (including negative gravitational potential energy) is already zero.
