Abstract

Cancer stem cells (CSCs) are a tumor cell subpopulation that drives tumor progression and metastasis, leading to poor overall survival of patients. In colorectal cancer (CRC), hyper-activation of Wnt/β-catenin signaling by mutation of both Adenomatous polyposis coli (APC) and K-Ras increases the size of the CSC population. We previously showed that the CPD0857 inactivates Wnt/β-catenin signaling by promoting ubiquitin-dependent proteasomal degradation of β-catenin and Ras proteins, thereby decreasing proliferation and increasing apoptosis of CRC lines. CPD0857 also decreased growth and invasiveness of CRC cells harboring mutant K-Ras resistant to EGFR mAb therapy. Here, we show that CPD0857 treatment decreases proliferation and increases neuronal differentiation of neural progenitor cells (NPCs). CDP0857 effectively reduced expression of CSC markers and suppressed self-renewal capacity. CPD0857 treatment also inhibited proliferation and expression of CSC markers in D-K-Ras MT cells carrying K-Ras, APC and PI3K mutations, indicating inhibition of PI3K/AKT signaling. Moreover, CPD0857-treated xenograft mice showed regression of tumor growth and decreased numbers of CSCs in tumors. We conclude that CPD0857 could serve as the basis of a drug development strategy targeting CSCs activated through Wnt/β-catenin-Ras MAPK-PI3K/AKT signaling in CRCs.

**Keywords:** Colorectal cancer, Cancer stem cell, Neural progenitor cell, Wnt/β-catenin, K-Ras
1. Introduction

Colorectal cancer (CRC) is one of the most common cancers and the second leading cause of cancer-related deaths globally [1]. CRC is a stem cell disease that occurs when an intestinal stem cell (ISC) escapes control and gives rise to a cancer stem cell (CSC) [2-5]. CSCs, also known as tumor-initiating or tumor-propagating cells, are a tumor cell subpopulation that can self-renew and differentiate into new tumors; thus, they contribute to tumorigenesis, metastasis and relapse [1,6-8]. Consequently, identifying and targeting factors involved in CSC activation has emerged as a promising CRC therapy [5,9].

The intestinal crypt stem cell niche, a unique microenvironment that enables optimal stem cell function, contains numerous molecular and cellular effectors [10]. If aberrant signaling is activated and maintained in that niche, neoplasias may emerge [10,11]. CRC occurs through genetic transformation in Wnt/β-catenin and RAS/ERK signaling pathways, both of which maintain normal ISC self-renewal and proliferation [11]. The Wnt/β-catenin pathway in particular supports ISCs and intestinal homeostasis [11,12]. Approximately 90% of CRC patients harbor loss-of-function mutations in the gene that encodes Adenomatous polyposis coli (APC) [13], a mutation that promotes nuclear accumulation of the Wnt effector β-catenin and leads to clonal expansion of ISCs and CRC initiation [13,14]. Subsequent adenoma progression is induced by a secondary oncogenic K-Ras mutation, which occurs in 40-50% of CRC [14,15]. K-Ras mutation does not by itself result in CSC activation [16,17]. However, oncogenic K-RAS mutation results in CSC activation involving malignant conversion in the presence of an APC mutation [18,19]. Regulation of oncogenic K-Ras through the Wnt/β-catenin pathway is a key for the interaction between the Wnt/β-catenin and RAS/ERK signaling pathways [5,19].

Nerve cells play an important role in tumor growth, invasion and metastasis and are considered components of the cancer microenvironment [1,20]. Cancer cells attract nerve fibers and stimulate nerve outgrowth by secreting neurotrophic factors [1,21-23]. Conversely, nerve fibers can infiltrate the tumor microenvironment and promote tumor growth and cancer cell dissemination [1,24]. Also, various pleiotropic signaling molecules control self-renewal and differentiation of neural progenitor cells (NPCs) [1,25]. Thus, targeting cancer and neurogenesis may be promising in terms of development of cancer therapy. Therefore, we asked whether a compound that we identified previously can induce neuronal differentiation of NPCs to suppress tumorigenesis and inhibit growth of a CRC-mediated tumor.

Previously, we performed a high throughput screen (HTS) using a dual cell-based screening system to identify a small molecule that decreased levels of both β-catenin and Ras proteins by inhibiting Wnt/β-catenin and Ras/ERK signaling. Using this system, we identified CPD0857 as an active compound. Thus, we asked whether
CPD0857 could promote neuronal differentiation of NPCs and inhibit tumor growth and progression in vivo and in vitro. Here, we show that CPD0857 effectively promotes neuronal differentiation of NPCs compared to other chemotherapeutic agents and significantly reduces subpopulation of CRC causing cancer drug resistance through inhibition of Wnt/β-catenin-Ras MAPK-PI3K/AKT signaling.

2. Materials and Methods

2.1. Cell Culture

CRC cell lines, including HT29, HCT116, HCT15, SW480, Caco2, RKO and LoVo, were purchased from the American Type Culture Collection (ATCC, Manassas, VA, USA). Isogenic cell lines (DLD-1 (D)-K-Ras WT, D-K-Ras MT & PI3K WT, and D-K-Ras MT & PI3K MT) were provided by B. Vogelstein (John Hopkins University School of Medicine, Baltimore, MD, USA). HEK293 and HEK293-TOP flash reporter cells were grown in DMEM (Gibco) containing 10% fetal bovine serum (FBS), 100 U/mL penicillin, and 10 μg/mL streptomycin at 37 °C. Human CRC lines were grown in RPMI 1640 (Gibco) containing 10% fetal bovine serum (FBS), 100 U/mL penicillin, and 10 μg/mL streptomycin at 37 °C.

2.2. Sphere Forming Assay

Serum-free medium used for sphere culture was composed of DMEM/F12 medium supplemented with 100 IU/ml penicillin, 10 μg/ml streptomycin, and 20 ng/ml human recombinant epidermal growth factor, 20 ng/ml human recombinant basic fibroblast growth factor, and 2% B27 supplement (Invitrogen, USA). CRC cells were seeded at a density of 2x10⁴ (n=3) cells/plate in ultra-low attachment 6-well plates for 5 days and then treated with varying drug doses for 72 hours. Relative numbers and sizes of colospheres were measured using Image J software.

2.3. Screen for Drugs that Promote Neuronal Differentiation

Neural Progenitor Cells (NPCs) were surgically extracted from the forebrain of E14.5 rats and maintained in an undifferentiated state by culture in DMEM/F12 with 10 ng/mL bFGF (Peprotech). Among phenotypes analyzed were cell number and morphology, as assessed by analysis of phase contrast images of cells after 48 h.

2.4. Immunoblotting Assay

Cells or tissues were gently lysed in RadioImmunoPrecipitation Assay (RIPA) buffer (Upstate Biotechnology, Lake Placid, NY, USA) for 1h on ice and centrifuged at 12,000rpm at 4°C for 15 min. Lysates were boiled for 5
min at 95℃ in SDS sample buffer and separated on 10% SDS-PAGE. After blocking, membranes were incubated first with primary antibodies and then with a peroxidase-conjugated secondary antibody. Bound secondary antibody (anti-mouse or anti-rabbit 1:10,000) was detected using the enhanced chemiluminescence (ECL) reagent (Santa Cruz Biotechnology). Images were taken using the luminescent image analyzer LAS-3000 (Fujifilm, Tokyo, Japan).

2.5. Immunohistochemistry and Immunocytochemistry

For immunohistochemistry, xenograft tissues were dissected and fixed in 4% paraformaldehyde (PFA) at 4℃. Paraffin sections were incubated with primary antibody at 4℃ for 18h. For immunocytochemistry, cells cultured on coverslips were fixed with 4% PFA/PBS for 2h and immune-stained after permeabilizing with 0.2% Triton X-100. Cells and tissues were then incubated with indicated primary antibodies overnight at 4℃, followed by Alexa Fluor 488 (Life Technologies, Carlsbad, CA, USA) or Alexa Fluor 555 (Life Technologies) secondary antibodies at room temperature for 1h and counterstained with 4′-6′diamidino-2-phenylindole (DAPI) (Boehringer Mannheim, Mannheim, Germany). Images were visualized using confocal microscopy (LSM5 PASCAL; Zeiss, Jena, Germany). Values obtained from at least three independent experiments were averaged and reported as mean±SD. Student’s two-tailed t test was used to compare two experimental groups.

2.6. Fluorescence-Activated Cell Sorting Analysis

For FACS, cells were gently dissociated and filtered through cell strainers (70 μm; BD Falcon) followed by incubation with conjugated primary antibodies. Cell surface markers were analyzed with a FACS Vantage SE flow cytometer (BD Biosciences) equipped with FlowJo software (TreeStar), and 10,000 events were recorded for each sample.

2.7. Animal Studies

Animal experimental procedures were approved by the Institutional Animal Care and Use Committee of the Yonsei Laboratory Animal Research Center. BALB/c nu/nu mice were purchased from the Central Lab Animal Inc. (Seoul Korea). All animals were housed in filter-topped shoebox cages equipped with a computerized environmental control system. Room temperature was maintained at 24℃ with 40–70% relative humidity. After acclimatization for 1 week, mice were subcutaneously injected with 1 × 10^6 DLD-1-K-Ras mutant (D-K-Ras MT) cells in 200 μl phosphate-buffered saline/Matrigel (1:1) in the dorsal flank. When mean tumor volumes reached ~
mice were randomly divided into two groups (four per group) and administered either CPD0857 suspended in 0.5% methyl cellulose/0.5% Tween 80 or vehicle intraperitoneally at a drug dose of 25 mg/kg, twice a week. Tumor volume was measured every 3–4 days using Vernier calipers, applying the formula: \( \pi/6 \times \text{length} \times \text{width} \times \text{height} \). Animals were euthanized when tumor volume exceeded 1500 mm\(^3\). Tumors were then excised, weighed, and fixed in 4% paraformaldehyde for further analysis.

2.8. Antibodies and Reagents

Antibodies used in this study were anti-β-actin (Santa Cruz Biotechnology, Santa Cruz, CA, USA), anti-PCNA (Santa Cruz Biotechnology), anti-TUJ1 (Abcam Inc.), anti-Nestin (Abcam Inc.), anti-Ki67 (Sigma-Aldrich), anti-BrdU (Sigma-Aldrich), anti-CD133 (Sigma-Aldrich), anti-CD44 (Abcam Inc.), anti-EpCAM (Abcam Inc.), anti-panRas (Upstate Biotechnology, Lake Placid, NY, USA; Abcam Inc., Cambridge, MA, USA), anti-β-catenin (Cell Signaling Biotechnology, Beverly, MA, USA), anti-pERK (Thr202/Tyr204) (Cell Signaling Biotechnology), anti-BrdU (Sigma-Aldrich), and HRP-conjugated anti-mouse (Bio-Rad Laboratories, Hercules, CA, USA). Fluorescent anti-rabbit secondary antibodies (Calbiochem, La Jolla, CA, USA) were used for detection by a luminescent image analyzer, LAS-3000 (Fujifilm, Tokyo, Japan).

2.9. Statistical Analysis

Statistical analyses were performed using Excel statistical tools or Prism 5 (GraphPad Software). Where differences between treatment groups were experimentally hypothesized, statistical differences between two groups were analyzed using Student’s \( t \)-test (\( *P < 0.05 \), \( **P < 0.005 \), and \( ***P < 0.0005 \)). ANOVA tests (Tukey’s multiple comparison test) were used to test hypotheses about effects in multiple groups.

3. Results

3.1. Neuronal differentiation activity of various compounds following inhibition of Wnt/β-catenin signaling

Colorectal cancer (CRC) is generally characterized by higher β-catenin and Ras expression due to gene mutation [19,26]; thus identifying an inhibitor of both could eradicate aggressive and metastatic CRC. To screen for such compounds, we used the dual cell based screening system previously described [19,26]. Specifically, we used a 2,000-compound ChemDiv drug screening library platform to identify compounds that would decrease TOP-flash reporter activity in HEK293 TCF/LEF cell line. We acquired 100 compounds that inhibited reporter activity and then narrowed them to the 9 most effective and least toxic candidates. We then asked whether any of the 9
candidates promoted neuronal differentiation. As shown in Figure 1, to do so we assessed neuronal differentiation of primary NPCs derived from the E14.5 rat embryo forebrain in the presence or absence basic fibroblast growth factor (bFGF) of the active compound. Overall, compounds CPD966, CPD0004, CPD0857 and CPD2677 promoted NPC differentiation, despite co-treatment with bFGF (Figure 1A). Among compound candidates, CPD0857 exhibited the most potent differentiation effect based on analysis of neurite outgrowth (Figure 1B). We then treated NPCs with each of the 9 candidates plus valproic acid (VPA), either alone or combined with bFGF. VPA was used for positive control for neuronal differentiation of NPCs (Figure 1C). CPD0857 treatment reduced proliferating cell nuclear antigen (PCNA) activity and increased levels of the neuron-specific marker Tuj1, as shown by immunoblots (Figure 1C) and band intensity quantification (Figure 1D). To determine whether CPD0857 inhibits TOP-flash reporter activity we co-transfected NPCs with TOP-flash reporter plasmid and β-galactosidase and treated cells with bFGF in the presence or absence of compound. We observed decreased luciferase reporter activity by close to a half in the presence of CPD0857/bFGF relative to bFGF alone (Figure 1E). Given that CPD0857 treatment of cancer cells decreased β-catenin and Ras protein expression through ubiquitin-dependent proteasomal degradation in previous study [33], we focused on β-catenin and Ras protein stability by treating NPCs with CPD0857 dose dependently and assessing β-catenin and Ras protein levels. Treatment with CPD0857 significantly increased phosphor (p)-β-catenin and reduced levels of β-catenin and Ras protein including pAKT, which is downstream signaling factor of Ras (Figure 1F). Moreover, to confirm these effects, we transiently overexpressed HA-Ubiquitin (HA-Ub) vector in the NPCs and then treated cells with CPD0857 plus MG132 (10 μg/mL). Immunoprecipitation (IP) analysis of endogenous β-catenin and Ras proteins followed by anti-HA immunoblot indicated that both endogenous proteins were polyubiquitylated, and that polyubiquitylated proteins accumulated in MG132-treated NPCs (Figure 1G).

3.2. CPD0857 treatment alters NPC proliferation and differentiation.

We next determined whether CPD0857 blocks NPC proliferation induced by bFGF. The intermediate filament protein Nestin is an NPC marker expressed in undifferentiated progenitor cells in the developing central nervous system (CNS) [1,27]. As shown in from Figure 2A to 2C, high contents screening (HCS) analysis of Nestin and Ki67 staining indicated that CDP0857 reduced proliferation and increased differentiation in NPCs more potently than did AG1478, cetuximab, 5-fluoruracil (5-FU) and LY294002 treatment during 1 DIV (day in vitro), all reagents used in various chemotherapies (Figure 2A-C). We also confirmed that combining CDP0857 with bFGF had a greater effect on NPC differentiation than bFGF alone during 2 DIV based on immunofluorescent analysis.
of nestin (Figure 2D,E). RT-PCR analysis also indicated that nestin mRNA levels in the presence of CDP0857 with bFGF were significantly reduced compared with treatment with bFGF only (Figure 2F). Moreover, CDP0857 plus bFGF treatment of NPCs decreased BrdU incorporation (indicating decreased proliferation) and increased Tuj1 levels (Figure 2F), and proportions of BrdU-positive cells decreased while numbers of Tuj1-positive cells increased following co-treatment with CDP0857 plus bFGF (relative to treatment with bFGF only (Figure 2G-I).

3.3. Effects of CDP0857 on CRC cells carrying K-Ras, APC and PI3K mutations

Oncogenic K-RAS plays a crucial role in CSC activation [19,26]. We observed that both the size and number of spheres (SPs) significantly decreased dose-dependently in SPs of D-K-Ras MT cells harboring APC and PI3K mutations following CDP0857 treatment (Figure 3A,B). After confirming that these were D-K-Ras MT cells based on high expression of the CSC markers CD44 and CD133, we observed lower expression of CSC markers in SPs treated with CDP0857 relative to vehicle controls (Figure 3C,D). We then used fluorescence-activated cell sorting (FACS) to quantify CD44- or CD133-positive cells in SPs and found that the number of CD44-positive cells in CDP0857-treated SPs was 32.7% less than that seen in vehicle controls. Consistently, the number of CD133-positive cells in CDP0857-treated SPs decreased by 34.4% (Figure 3E).

3.4. CDP0857 inhibits tumorigenesis in CSCs harboring K-Ras, APC and PI3K mutations

To investigate CDP0857 activity in colon cancer lines, we examined and quantified CD44 and CD133 expression in various colon cancer lines such as CCD-18Co, HCT15, HT-29, Caco2, SW480, SW480APC15, HCT116 (HAE6) MT, HCT116 (HAE6) WT, D-K-Ras WT, SW480APC38, HCT116 and D-K-Ras MT (Figure 4A). We observed significantly increased staining for both CD44 and CD133 in the D-K-Ras MT line (Figure 4A). Therefore, we performed mouse xenograft studies using D-K-Ras MT cells harboring APC and PI3K mutations and treated mice in vivo with CDP0857 (intraperitoneally (i.p.), 25 mg/kg). As shown in Figure 4B, CDP0857 administration significantly reduced size of D-K-Ras MT tumors relative to vehicle-treated xenograft mice, and tumor volume in vehicle-treated mice was much greater than that seen in CDP0857-treated mice (Figure 4C). When we assessed CD44 and CD133 expression levels in these mice, CDP0857 treatment reduced levels of both CSC markers based on FACS analyses of tumors excised from xenografted mice (Figure 4D). We then tested CDP0857 effects on Wnt/β-catenin and Ras/ERK signaling using tumors excised from CDP0857- or vehicle-treated xenograft mice. CDP0857 treatment significantly decreased levels of activated proteins found in both pathways, such as β-catenin, Pan-Ras, and p-ERK (Figure 4E). Also, expression of PCNA, CD133, CD44 and
EpCAM (epithelial cell adhesion molecule) decreased relative to controls following CPD0857 treatment, based on immunohistochemical analysis of tumors generated by xenografts (Figure 4E).

4. Discussion

*K-Ras* mutations play an important role in promoting characteristics of CSCs, which are a critical cause of malignancies leading to lethality of CRC patients [1,15,28]. CSC induction by both APC and *K-Ras* mutations synergistically activate CRC tumorigenesis [1,15,19]. The Ras/extracellular-signal-regulated kinase (ERK) pathway interacts with Wnt/β-catenin signaling during CRC tumorigenesis and metastasis, and levels of both β-catenin and RAS proteins positively correlate with each other in CRC harboring APC mutations [1,15]. There are several reports that APC and *K-Ras* mutations co-occur at different stages of CRC tumorigenesis and metastasis [19,26]. Moreover, recent studies support the idea that interaction of Wnt/β-catenin with Ras/ERK pathways during CSC tumorigenesis increases malignancy [19]. Generally, *K-Ras* regulates ERK and phosphatidyl inositol 3-kinase (PI3K)-Akt signaling pathways [19,29]. *K-Ras* mutations alone do not significantly induce malignant transformation of the mouse intestinal epithelium; however, additional APC mutations synergistically enhance tumor growth and metastasis to liver and lung [16,19,29,30]. Moreover, patients with metastatic CRC bearing *K-Ras* mutations overexpress epidermal growth factor receptor (EGFR), a transcriptional target of the Wnt/β-catenin pathway, and are resistant to EGFR mAb drugs such as cetuximab and panitumumab used as CRC chemotherapy [1,31,32]. Thus, it is necessary to develop drugs that simultaneously target the Wnt/β-catenin and Ras/ERK pathways for effective CRC treatment. In this study, we demonstrate that CDP0857 is a chemical compound that inhibits CSCs of CRC tumors by inhibiting Wnt/β-catenin and Ras/ERK pathways [33].

Infiltration of the cancer microenvironment by nerve fibers occurs with cancer progression and is a sign of poor prognosis[23]. Moreover, the CRC microenvironment is rich in autonomic nerve fibers [19,29,34]. Recent studies showed that a fraction of CSCs derived from patients with colorectal carcinoma can generate neurons that function in tumor neurogenesis and tumor growth [23]. To assess whether CDP0857 regulates NPC proliferation we used primary NPCs derived from the E14.5 rat embryo forebrain. CDP0857 treatment of these cells effectively induced neuronal differentiation. Basic fibroblast growth factor (bFGF) modulates neurogenesis and NPC proliferation, *in vivo* and *in vitro* [19,29,35]. Treatment of NPCs with CDP0857 resulted in a phenotype similar to that seen in the absence of bFGF, namely, differentiation marked by neurite outgrowth and decreased proliferation. Valproic acid (VPA) reportedly induces NPC differentiation and inhibits growth [19,29,36]; CDP0857 treatment reduced PCNA activity and BrdU incorporation and increased expression of the neuronal
marker Tuj1 levels beyond effects seen in the presence of VPA. Also based on staining for the NPC marker nestin, CDP0857 decreased proliferation and increased differentiation of NPCs more potently than did the commonly used anticancer drugs AG1478, cetuximab, 5-fluorouracil (5-FU) and LY294002. These results indicate that CDP0857, which inhibits Wnt/β-catenin signaling, suppresses NPC proliferation and promotes neuronal differentiation.

CDP0857 also inhibited self-renewal capacity of CRC cells in SPs of D-K-Ras MT cells harboring APC and PI3K mutations. Likewise, CDP0857 treatment of various colon cancer lines decreased levels of the cell surface proteins CD44 and CD133, which are CSC markers. To confirm these results in vivo, we performed mouse xenograft studies using D-K-Ras MT cells harboring APC and PI3K mutations and treated mice with CDP0857. CDP0857 treatment significantly reduced tumor size and volume of D-K-Ras MT cells harboring these mutations, and tumors excised from xenograft mice showed significantly reduced expression of CD44, CD133 and EpCAM and of active forms of factors in the Wnt/β-catenin and Ras/ERK pathways. Also, CDP0857 treatment decreased expression of proliferation markers. Overall, although additional research is needed to define the relative contributions of pathways involved, our results suggest that CDP0857 could serve as a potential therapeutic agent to inhibit CSC activation in CRC associated with neuronal differentiation.

Figure 1. Screening drugs promoting neuronal differentiation of the neural progenitor cells (NPCs) via inhibiting Wnt/β-catenin signaling. (A) 9 lead compounds selected by Dual High-throughput Screening System which was described previously [33] were tested for measuring neuronal differentiation using primary NPCs derived from the E14.5 rat embryo forebrain. NPCs were treated with 9 compounds (10 μM) for 48 h in the presence or absence of 20 ng/ml bFGF. Micrographs were taken at a magnification of 200×. (B) Neurite outgrowths were quantified using ImageJ software. All data are shown as mean ± SD for at least 3 independent images. ***P < 0.005, 2-sided t test. (C) NPCs were grown for 18 h in N2:B27 (1:1) medium containing bFGF and treated with valproic acid (VPA, negative control, 1mM) and each compound (10 μM). Whole cell lysates (WCLs) were immunoblotted
using indicated antibodies. (D) Relative band intensity shown in (C) were quantified using Image J software (n=3). 
Red arrows indicate the significant decreases or increases of PCNA or Tuj1 in NPCs, respectively. (E) NPCs were 
transfected with Topflash reporter plasmid and co-transfected with β-galactosidase. At 24 hours later the growth 
medium containing transfection reagents was removed and replaced with N2 media with or without 25 μM 
CDP0857 for a further 24 h. Cells were then harvested and luciferase reporter assays were performed. (F) Western 
blot (WB) analysis of NPCs using indicated antibodies. (G) Ubiquitylation assay of β-catenin and Ras proteins in 
indicated lysates of NPCs. Cells were transduced with HA-Ub plasmids and then treated a day later with or without 
CPD0857 for 24 hrs. Cells were also treated with MG132 during 6 hours before harvest. Immunoprecipitation (IP) 
was performed with β-catenin or Ras antibodies. WCLs were analyzed by WB for indicated antibodies (n=2). 
Statistical t-test analysis was performed to evaluate significance (**P < 0.0005).

Nuclei were counterstained with DAPI. (H, I) Percentages of relative numbers of BrdU-positive cells (H) and Tuj1-positive cells (I). Values correspond to mean ± SD. ANOVA tests were performed to calculate significance (*P < 0.05, **P < 0.005, ***P < 0.0005). bFGF, basic fibroblast growth factor; BrdU, 5-bromo-2-deoxyuridine; DAPI, 4,6-diamidino-2-phenylindole.
Figure 3. Effects of CDP0857 on sphere formation and cancer stem cell activation of colorectal cancer (CRC) cells carrying K-Ras, APC and PI3K mutations. (A-C) D-K-Ras WT and D-K-Ras MT cells harboring mutation both APC and PI3K were seeded at a density of 2x10^4 (n=3) cells/plate in ultra-low attachment 6 well plates for 5 days and were treated with varying doses of CDP0857 for 72 hours. (B) Relative numbers and sizes of colospheres were measured using Image J software. (C) D-K-Ras MT cells harboring mutation both APC and PI3K were seeded at a density of 2x10^4 cells/well in 24 well plates and were treated with varying doses of CDP0857 for 24 hours. Immunofluorescent labeling of CD133 and CD44. Nuclei were counterstained with DAPI. Images were obtained using a Zeiss confocal microscope. (D) Quantification of CD133 and CD44 double positive populations in each immunostained tumor cells. (E) The relative numbers of CD133- or CD44- positive cells were quantified by fluorescent-activated cell sorter (FACS) analyses.
Figure 4. CDP0857 inhibits progression of tumor with mutation of K-Ras, APC and PI3K by reducing cancer stem cell populations. (A, upper) Colon cancer cell lines were subjected to immunofluorescence analysis with indicated antibodies, and nuclei were counter-stained with DAPI. Scale bars, 20 μm. (A, lower) Quantification of CD133 and CD44 double positive populations in each immunostained tumor cells. Images were captured using a Zeiss confocal microscope. (B) D-K-Ras MT cells harboring mutation both APC and PI3K were subcutaneously injected into flanks of BALB/c nude mice (n=4). Mice were treated for 21 days by intra peritoneal (I.P.) injection with vehicle or with 25 mg/kg CDP0857 once every three days. Gross images showing representative tumor cases treated with drug, with enlarged tumor images for each case presented at the bottom. (C) Tumor volumes of mice
treated with vehicle or CDP0857 were measured with the Vernier calipers every 3 days. (D and E) Excised tumors were used for FACS analysis (D) and immunoblot analysis (E) with indicated antibodies. (E, upper) Paraformaldehyde (PFA)-fixed paraffin sections from excised tumor were incubated with antibodies against β-catenin, pan-Ras, pERK, PCNA, CD133, CD44, and EpCAM. (E, lower) Expression of antibodies in the immunostained tumor tissues in each representative xenograft tumor was quantified using Image J software. Images were captured using a Zeiss confocal microscope. Representative images were selected from at least 3 different fields. All data are shown as mean ± SD for at least 3 independent specimens. **P < 0.005, ***P < 0.0005, 2-sided t test.
