Abstract: Background: To investigate the effects of the COVID-19 lockdowns on the vasculopathic population. Methods: The Divisions of Vascular Surgery of the southern Italian peninsula joined this multicenter retrospective study conducted through cross-sectional survey. Each received a 13point questionnaire, investigating the hospitalization rate of vascular patients in the first 11 months of the COVID-19 pandemic and in the preceding 11 months. Results: 27 out of 29 Centers were enrolled. April-December 2020 (7092 patients) vs 2019 (9161 patients): post-EVAR surveillance, treatment for Rutherford category 3 peripheral arterial disease, and asymptomatic carotid stenosis revascularization significantly decreased [1484 (16.2%) vs 1014 (14.3%), p=0.0009; 1401 (15.29%) vs 959 (13.52%), p=0.0006; and 1558 (17.01%) vs 934 (13.17%), p<0.0001, respectively]; while revascularization or major amputations for chronic limb-threatening ischemia, and urgent revascularization for symptomatic carotid stenosis significantly increased [1204 (16.98%) vs 1245 (13.59%), p<0.0001; 355 (5.01%) vs 358 (3.91%), p=0.0007; and 153 (2.16%) vs 140 (1.53%), p=0.0009, respectively. Conclusions: The suspension of elective activities during the COVID-19 pandemic caused a significant reduction in asymptomatic carotid stenosis revascularization, treatment for Rutherford 3 peripheral arterial disease, post-EVAR surveillance. Contestually, we observed a significant increase in urgent revascularization for symptomatic carotid stenosis, and revascularization or major amputations for chronic limb-threatening ischemia.

Keywords: COVID-19; carotid stenosis; abdominal aortic aneurysm; chronic limb-threatening ischemia; amputation; deep venous thrombosis

1. Introduction

The Coronavirus disease 2019 (COVID-19) pandemic has changed lifestyles and working activities worldwide. Following the publication of the Italian government decree in March 2020, three-month strict lockdown measures were implemented countrywide to avoid social contact. Hospital-related routines were interrupted to give priority to the management of COVID -19 cases; in particular, outpatient and elective surgery were post-poned.

Similar prevention and public health interventions were implemented from the second half of September up to the beginning of December 2020 in response to the second wave of the pandemic. Furthermore, except for situations of proven urgency, the quality of diagnostic and therapeutic care of General Medicine in Southern Italy was impacted negatively during the lockdowns, affecting the diagnosis, management and surveillance of the vascular patients.

This study was conducted to assess the eventual impact of suspension of elective vascular surgery on the incidence rates of complications caused by common vascular conditions compared to the pre-pandemic period.

2. Materials and Methods

A multicenter retrospective cross-sectional study was carried out: the majority of public vascular surgery wards, or accredited with the National Health System (NHS),

located in the south of the Italian peninsula were enrolled (i.e., the regions of Campania, Molise, Basilicata, Puglia, Calabria; population: 12,646,486; area: 62,809 km², figure 1).

Figure 1. The five regions of the southern Italian peninsula (reproduced with permission from Atlante Geografico Mondiale. Milan, Italy: Touring Club Italiano, 2021).

Even though healthcare policies are issued at a regional level in Italy, the above-mentioned regions implemented similar COVID-19 restrictions.

Twenty-seven vascular surgery divisions joined the study; only two centers (one public and one private) declined to participate due to the lack of human resources for data collection. A 13-item questionnaire was provided, asking the number of patients that underwent:

- 1) open repair or endovascular aneurysm repair (EVAR) for asymptomatic abdominal aortic aneurysm (AAA);
 - 2) open repair or EVAR for primary ruptured or symptomatic AAA;
 - 3) duplex or computed-tomography scans performed for post-EVAR surveillance;
- 4) Previous EVAR treated again (in an open or endovascular fashion) for recurring symptomatic or ruptured AAA, or for endoleak at risk of AAA rupture (type 1, 3, or 2 with sac expansion);
- 5) open, or endovascular treatments for thrombotic, non-embolic, acute lower limb ischemia;
- 6) treatments for Rutherford category 3 peripheral arterial disease (R3-PAD), in socially active patients with very short distance intermittent claudication (less than 50 mt. on the flat), not responsive to best medical therapy, and asking for a resolutive treatment to improve their life-style;
- 7) open or endovascular revascularizations for chronic limb-threatening ischemia (CLTI);
 - 8) CLTI patients who have had a thigh or leg amputated;
- 9) open or endovascular revascularizations for asymptomatic severe internal carotid artery (ICA) stenosis;

- 10) Asymptomatic severe ICA stenosis on surgical waiting list, complicated to total obstruction (with or without neurological symptoms);
 - 11) symptomatic ICA stenosis operated in urgency;
 - 12) conservative or surgical treatments for venous ulcers;
- 13) diagnosis of deep vein thrombosis (DVT), also from requests of consultation from the emergency room or any medical/surgical divisions.

The aim was to compare these vascular surgery activities before (11 months pre-COVID-19) and during the COVID-19 pandemic (11 months since the beginning of the pandemic).

Indications for carotid, AAA, CLTI, and venous surgery, as well as the diagnosis of vascular diseases, are those reported in the current, well-known, international guidelines.

Informed consent for the present study was waived because of the retrospective and aggregated nature of the study analysis. Being an observational study, according to the Italian law, a mandatory approval is not needed.

Clinical characteristics were described with absolute and relative (percentage) frequencies. Qualitative variables were compared using the chi-square test. Percentage differences for the collected variables (delta) between pre-COVID-19 and COVID-19 periods were computed. A two-tailed p-value <0.05 was considered statistically significant. All statistical analyses were carried out using the STATA software version 17 (StataCorp LLC, TX, USA).

3. Results

Information on 19,603 cases was collected: 11,129 (56.8%) during the pre-COVID period (Table 1a), 8,474 (43.2%) during the COVID-period (Table 1b).

#12	Treatment for venous ulcers	588 (6.42)	461 (6.5)	0.80	-21.60
#13	Diagnosis of deep vein thrombosis	753 (8.22)	695 (9.8)	0.0004	-7.70

When only April 2019 and April 2020 were compared, the significant decrease in imaging for post-EVAR surveillance, treatment for R3-PAD, and asymptomatic ICA stenosis revascularization was confirmed (19.43%, vs 9.98% p<0.0001; 18.06% vs 9.38%, p<0.0001; 17.11% vs 10.38%, P: 0.0006, respectively), as well as the significant increase in open or endovascular revascularization for CLTI, major amputations for CLTI, and the diagnosis of DVT (17.76% vs 4.86%, p<0.0001; 8.58% vs 4.65%, p=0.002; 13.37% vs 9.19%, p=0.01, respectively). Furthermore, a significant decrease in the number of patients requiring further treatment after EVAR (1.69% vs 1%, p=0.006) and a significant increase of patients treated for acute, thrombotic lower limb ischemia was found (8.78% vs 4.96%, p=0.005, table 3).

Table 3. Summary of the responses to the questionnaire for the COVID month of April 2020, compared with the non-COVID month of April 2019.

	Activities	April 2019 (no COVID) (n= 947) n (%)	April 2020 (COVID) (n= 501) n (%)	p- value	Delta %
#1	Open repair / EVAR for asymptomatic AAA	99 (10.45)	53 (10.58)	0.91	-46.46

Groupings of the initial months of 2020 (January-February vs March-April) were characterized by a significant decrease of imaging for post-EVAR surveillance, treatment for R3-PAD, and asymptomatic ICA stenosis revascularization (16.11% vs 10.89%, p=0.0001; 15.4% vs 11.73%, p=0.005; 16.36% vs 10.99%, p=0.0001, respectively), while an increase of major amputations for CLTI and diagnoses of DVT was shown (6.89% vs 3.61%, p<0.0001 and 12.1% vs 8.79%, p=0.004, respectively). Furthermore, a significant increase in the treatment of acute thrombotic lower limb ischemia occurred (7.91% vs 5.49%, p=0.01, table 8).

Table 8. Summary of the responses to the questionnaire for the COVID months of March/April 2020, compared with the non-COVID months of January/February 2020.

	Activities	January/ February 2020 (no COVID) (n= 1968) n (%)	March/ April 2020 (COVID) (n= 1074) n (%)	p- value	Delta %

#10	Asymptomatic severe ICA stenosis on surgical waiting list complicated to total obstruction	0 (0)	0 (0)	-	
#11	Symptomatic ICA stenosis operated in urgency	16 (1.53)	13 (1.61)	0.86	-18.75
#12	Treatment for venous ulcers	67 (6.41)	61 (7.54)	0.35	-8.96
#13	Diagnosis of deep vein thrombosis	96 (9.19)	76 (9.39)	0.88	-20.83

During the pandemic period from March 2020 to January 2021, 36/1,713 (2.1%) patients who presented with CLTI, 33/501 (6.6%) patients who required major amputation, and 9/207 (4.4%) patients with stroke or transient ischemic attacks tested positive for COVID-19.

The numbers of EVAR or open repair for asymptomatic AAA, treatment for venous ulcers, and severe ICA stenosis >80% (according to the European Carotid Surgery Trial, ECST, parameters) on operating waiting list complicated to total obstruction (detected at duplex control before revascularization, or because become symptomatic) did not change throughout the study period.

4. Discussion

Early identification of life-threatening vascular conditions, which are mostly asymptomatic, is key. Changes during the COVID-19 pandemic could have affected patient prognosis. Several researchers, clinicians, and policymakers have been trying to understand the real impact of the pandemic on clinical activities.

A study carried out in the metropolitan city of Bologna, Italy, focusing on the first 30 days of the COVID-19 pandemic showed that the number of surgical interventions was similar to those recorded in 2018 and 2019. No differences were found in the acute/emergency setting, including interventions for acute ischemia, although SARS-CoV-2 infections trigger thrombogenic mechanisms [1]. On the contrary, in The Netherlands it has been reported that during the lockdown period of March 16th until April 30th 2020, there was a statistically significant increase in CLTI severity and the rates of major amputations, compared to the same time period of the two previous years. No difference in vascular surgical care for patients with a AAA has been observed [2].

A US cross-sectional study focusing on the period from April 14^{th} to 24^{th} 2020 showed a significant impact on the practice of vascular surgery across the country, with unprecedented number of surgical cases cancelled, and changes in on-call schedules. The

majority of continued elective cases were on aortic repair and maintenance of dialysis function rather than peripheral arterial disease or venous procedures [3]. Similarly, in Indochina almost all vascular interventions were suspended during the COVID-19 outbreak [4].

Our multicenter study, covering more than one-fifth of the Italian geographical area and population, over a longer time-period (11 months before and 11 months during the COVID-19 pandemic) showed a significant decrease in elective interventions for:

- prophylactic ICA revascularization during each month of the pandemic compared to the prior year, as well as during the first two months of the pandemic compared to the prior two months;
- imaging for post-EVAR surveillance from April to June, 2020, compared to the corresponding time-period of 2019, as well as during the first two months of the pandemic (March-April, 2020) in comparison with the two months before it (January-February, 2020);
- treatment for R3-PAD during the first two months of the pandemic in comparison with the two prior months, and in April 2020 and January 2021 when compared with the corresponding month of the previous year.

On the other hand, a significant increase in urgent revascularization for symptomatic ICA stenosis, revascularization for CLTI, major amputations, diagnosis of DVT, open repair or EVAR for primary ruptured or symptomatic AAA, and treatment of acute, thrombotic lower limb ischemia.

The decrease of prophylactic ICA revascularization could be associated with the increased rate of urgent revascularization for symptomatic carotid stenosis.

Furthermore, the decrease in the treatment for R3-PAD in the first two months of the pandemic could explain the increased rate of revascularization and major amputation for CLTI in April and November-December 2020, and January 2021. Around 20% of patients with intermittent claudication experience deterioration of limb status over a 5-year period, and symptomatic deterioration is greatest within the first year after diagnosis [5].

Interestingly, in January 2021 (when the immediate pandemic restrictions were lifted) a major decrease in the treatment of R3-PAD and severe asymptomatic ICA stenosis persisted compared to pre-pandemic levels. Our analysis suggests that the delays may have further consequences in the coming months. Project 1 (Impact of COVID-19 on scheduled vascular operations) of the international Vascular Surgery COVID-19 Collaborative (VASCC) registry aims to answer this particular question. VASCC is a combined international effort to obtain prospective data on the impact of widespread vascular surgical care delays due to an international crisis or pandemic [6,7].

An increased rate of DVT during the first four months of the pandemic and of thrombotic acute lower limb ischemia recalls the prothrombotic effects of the SARS-CoV-2 infection [8,9]. The broad spectrum of clinical manifestations, affecting almost all organs and systems, is a consequence of the endothelial dysfunction and systemic inflammatory response. Endothelial cells activated by a hyperinflammatory state induced by viral infection may promote localized inflammation, increase reactive oxidative species production, and alter dynamic interplay between the procoagulant and fibrinolytic factors in the vascular system, leading to thrombotic disease not only in the pulmonary circulation but also in peripheral veins and arteries [10].

Although the US national trends in Vascular Surgical Practice showed a decreased rate of urgent and emergency aortic and carotid interventions, our study described an increased rate of open repair or EVAR for ruptures or symptomatic AAA, and of symptomatic carotid stenosis treated with urgency [11].

The constant trends of patients who underwent EVAR or open repair for primary asymptomatic AAA during the current pandemic could be associated with the positive organization of healthcare delivery in the participating centers, although no specific data was collected to support this hypothesis. Similar explanations could support the trends of

conservative or surgical treatment for venous ulcers, although they are managed in wards other than vascular surgery (i.e., vascular medicine and dermatology).

Several study limitations can be highlighted: some vascular diseases (e.g., thoracic or thoraco-abdominal aortic aneurysms and dialysis access) were not considered. Complex aortic procedures are often referred to specialist centers, and we thought numbers would have been too low. In Italy, arteriovenous fistulas are also performed by nephrologists. Likewise, varicose vein surgery was excluded based on its postponement caused by their low priority. We evaluated only the first eleven months of the COVID-19 pandemic against the corresponding 2019 months; as such, inter-annual variability cannot be excluded. The stratification of the findings based on SARS-CoV-2 positivity was not always performed: the infection could have increased the incidence of some vascular diseases (e.g., DVT). Asymptomatic severe ICA stenosis that progressed to occlusion (and thus was managed non surgically) could have been missed, since it can cause cerebral ischemia which can be managed in different medical wards (e.g., stroke unit, intensive care unit, neurology, internal medicine) and thus under-reported.

5. Conclusion

The interruption of elective surgery during the COVID-19 pandemic caused decreased rates of prophylactic carotid revascularization, treatment for very short-distance intermittent claudication, and post-EVAR surveillance. Those findings are associated with the increased rate of urgent revascularization for symptomatic carotid stenosis, CLTI and subsequent major amputations.

The vascular community is called upon to raise awareness of the dangers arising from restrictions in the management of these elective vascular patients during the pandemic crisis.

The long-term effects on the management of vascular patients should be evaluated in the near future.

Author Contributions: Conceptualization, EM, GS, LS, MF, GS, MZ, ARM, GA, GB, FB, UMB, EC, GC, GC, AC, SDV, CPD, LF, GI, FI, LI, GM, PM, MM, GN, VP, FP, FP, RP, DR, MRR, CR, PS, GV, PV, AMS; Methodology, EM, GS, LS, MF, GS, MZ, ARM, AB, PB, MB, EMC, FC, LC, ASDA, MDL, CD, DDL, GDN, AD, IF, AG, ANG, AL, MM, VM, AP, MP, AP, SP, RP, MT, AMS; Validation, EM, GS, LS, MF, GS, MZ, ARM, AB, PB, MB, EMC, FC, LC, ASDA, MDL, CD, DDL, GDN, AD, IF, AG, ANG, AL, MM, VM, AP, MP, AP, SP, RP, MT, AMS; Formal analysis, EM, GS, LS, MF, GS, MZ, ARM, AMS; Investigation, EM, GS, LS, MF, GS, MZ, ARM, AB, PB, MB, EMC, FC, LC, ASDA, MDL, CD, DDL, GDN, AD, IF, AG, ANG, AL, MM, VM, AP, MP, AP, SP, RP, MT, AMS; Resources, EM, GS, LS, MF, GS, MZ, ARM, GA, GB, FB, UMB, EC, GC, GC, AC, SDV, CPD, LF, GI, FI, LI, GM, PM, MM, GN, VP, FP, FP, RP, DR, MRR, CR, PS, GV, PV, AMS; Data curation, EM, GS, LS, MF, GS, MZ, ARM, AB, PB, MB, EMC, FC, LC, ASDA, MDL, CD, DDL, GDN, AD, IF, AG, ANG, AL, MM, VM, AP, MP, AP, SP, RP, MT, AMS; Writing—original draft preparation, EM, GS, LS, MF, GS, MZ, ARM, AMS; Writing – review and editing, EM, GS, LS, MF, GS, MZ, ARM, GA, GB, FB, UMB, EC, GC, GC, AC, SDV, CPD, LF, GI, FI, LI, GM, PM, MM, GN, VP, FP, FP, RP, DR, MRR, CR, PS, GV, PV, AB, PB, MB, EMC, FC, LC, ASDA, MDL, CD, DDL, GDN, AD, IF, AG, ANG, AL, MM, VM, AP, MP, AP, SP, RP, MT, AMS; Visualization, EM, GS, LS, MF, GS, MZ, ARM, AB, PB, MB, EMC, FC, LC, ASDA, MDL, CD, DDL, GDN, AD, IF, AG, ANG, AL, MM, VM, AP, MP, AP, SP, RP, MT, AMS; Supervision, EM, GS, LS, MF, GS, MZ, ARM, GA, GB, FB, UMB, EC, GC, GC, AC, SDV, CPD, LF, GI, FI, LI, GM, PM, MM, GN, VP, FP, FP, RP, DR, MRR, CR, PS, GV, PV, AMS; Project administration, EM, GS, LS, MF, GS, MZ, ARM, GA, GB, FB, UMB, EC, GC, GC, AC, SDV, CPD, LF, GI, FI, LI, GM, PM, MM, GN, VP, FP, FP, RP, DR, MRR, CR, PS, GV, PV, AMS; All authors have read and agreed to the published version of the manuscript.

Funding: This research received no external funding.

Institutional Review Board Statement: Ethical review and approval were waived. Being an observational study, according to the Italian law, a mandatory approval is not needed.

Informed Consent Statement: Patient consent was waived due to the retrospective and aggregated nature of the study analysis.

Data Availability Statement: Raw data was obtained from the vascular surgery divisions of the southern regions of the Italian peninsula and are readily available for presentation to the referees and the editors of the journal, if requested.

Acknowledgments: The authors gratefully acknowledge Edoardo Guarino, M Eng, M Sc, for the English revision of this manuscript.

Conflicts of Interest: The authors declare no conflict of interest.
