Gravity, Information and Accelerated Expansion

Abstract: The holographic principle states that the information about the volume of space is stored on its boundary. Assuming this holds, we can explain the aspects of gravity. The spacetime needs to be extended to 5D to explain gravity in this context. This naturally explains the four classical tests of gravity namely the gravitational redshift, the perihelion precession, the bending of light, and the gravitational time delay. We also show a novel way in which the universe expands in an accelerated manner at late times without the need for any form of dark energy.

Keywords: extra dimension; thermodynamics and gravity; accelerated expansion; universe-antiuniverse pair

1. Introduction

Our first encounter with gravity came from the realization of Newton of gravity as an attractive force between every two objects in the universe, mathematically described by the universal law of gravitation. Despite being experienced by us in daily life, gravity remains the most mysterious force of all. Einstein realized gravity not as a fundamental force but as a very abstract phenomenon arising from the curvature of spacetime induced by matter and encoded in the famous Einstein's field equation. General Relativity(GR) as we call Einstein's theory is a metric theory that beautifully explains every phenomenon observed at large scales to date. However, the theory is incompatible with another cornerstone and highly successful theory of Quantum Mechanics. Moreover being a metric theory, it admits certain unphysical solutions such as closed timelike curves and spacetime singularity. It also remains difficult to explain dark matter and dark energy within the framework of GR. The first link between thermodynamics and gravity came from black hole physics where there is an apparent connection between horizon area and the entropy of the black hole. Hawking[1] first showed that the area of the horizon(A) of a black hole is a non-decreasing function of time.

$$\frac{dA}{dt} \geq 0 \quad (1)$$

Bekenstein[2–4] took this further and asserted the equivalence of the horizon area with the thermodynamic parameter, entropy(S) as

$$S = \gamma A \quad (2)$$

where γ is a constant. The claim got a robust description when Hawking[5] derived the temperature of the black hole, thus making the relation between the area and entropy clear. Later, in 1995, Jacobson[6] derived Einstein's equation from the proportionality of entropy and horizon area together with the relation $dQ = TdS$ connecting heat, entropy, and temperature. There are also closely related follow-up articles[7–11]. Another work relating thermodynamics and gravity is due to Padmanabhan (see [12] for a review) and his collaborators[13–17]. These results suggest that gravity may be explained as an emergent phenomenon and have a thermodynamic

or entropic origin. Recently, Verlinde[18] proposed Newtonian gravity as a physical entropic force, caused by changes in the information associated with the positions of material bodies, although, this description of Newtonian gravity as a physical entropic force has been technically questioned too[19–22]. Our goal here is different, we are making no connection with the background spacetime metric $g_{\mu\nu}$ and are thus not set to derive Einstein's gravity as Jacobson and Padmanabhan did because we do not think that Einstein's approach of describing gravity as background spacetime curvature is the only and ultimate reality. We are also not justifying or falsifying the claim of Verlinde of Newtonian gravity as a physical entropic force. Since we are not using Einstein's approach of gravity as spacetime curvature, we explicitly show then, how can we explain the gravitational redshift, the modified equation of motion for both massive and massless particles, and the accelerated expansion of the universe. This way of describing gravity as a non-metric theory naturally does away with the inherent unphysical problems of a metric theory such as closed timelike curves and spacetime singularity. The study of type Ia supernova in 1998 by two independent projects, the Supernova Cosmology Project and the High-Z Supernova Search Team revealed an astonishing result that the universe is not only expanding but it is expanding at an accelerating rate [23]. The accelerated expansion of the universe is thought to have begun since the universe entered its dark-energy-dominated era roughly 5 billion years ago. The currently accepted theory of gravity, General Relativity, accounts for this accelerated expansion by introducing a small and positive value of the cosmological constant Λ . Alternative explanations such as phantom energy, quintessence are also hypothesized as the explanation of late time cosmic acceleration. Some explanations beyond four dimensions also exist such as the Dvali-Gabadadze-Porrati (DGP) model[24] which argues that gravity behaves as 5D at large distances while reducing to that of usual 4D gravity at short distances. However the precise nature of dark energy remains unknown. Alternative explanations are promising but have their own shortcomings, as was argued in[25] that the self-accelerating solution of DGP model[26] contains a ghost mode. Very intriguing arguments are presented in [27–30] that the universe should exist in pairs with their time oppositely related. The paper is organized as follows: we begin our discussion by understanding this new connection between gravity and "information" in the system. In section 3 we explain how the thermodynamic nature of our system changes the total energy and this leads to the extension of the spacetime to 5D. In section 4 we find the solution for a point mass in our theory. In section 5 we review the Quantum Focusing Conjecture(QFC)[31]. We briefly recall Casini's work on relative entropy and Bekenstein bound in section 6 and conclude the paper by putting forth a novel way in which the accelerated expansion of the universe happens at late times.

2. Some Terminology

Let us first define some quantities relevant to our discussion and approach. Consider the system consisting of a source mass M and a boundary. The "boundary" here is a data-storing surface such as a holographic screen. Motivated by the Bekenstein bound[32], let us define a quantity C_D as the maximum degrees of freedom associated with the mass M at a distance R from the boundary as¹

$$C_D = \frac{2\pi RM}{\hbar} \quad (3)$$

Another quantity C_I is defined as the maximum degrees of freedom available. This is assumed to follow the holographic principle[33,34] which has strong pieces of evidence from the AdS/CFT

¹ We set $k_B = c = 1$

correspondence[35] and black hole physics[3,5], such that the information about the volume of space is stored on the boundary. Thus we assume that the total degrees of freedom is given by

$$N = \frac{A}{l_p^2} \quad (4)$$

where A is the surface area of the boundary and l_p is the Planck length. Therefore

$$C_I = N = \frac{A}{l_p^2} \quad (5)$$

The "disorder" D in the system which gives the ratio of the maximum degrees of freedom of the mass M to the maximum available degrees of freedom is therefore given by²

$$D = \frac{C_D}{C_I} \quad (6)$$

Now that we have defined some important quantities needed to present our approach, we turn toward a specific and important property of the boundary which is the temperature T . This can be found by invoking the use of the boundary as a holographic screen that can store data, thus as an object comes near this holographic screen, its total energy(p^0) is stored on the boundary as evenly bits of information N . Since the distribution is even, we can use our good old equipartition rule of thermodynamics to find the temperature of the boundary as

$$p^0 = \frac{1}{2}NT \quad (7)$$

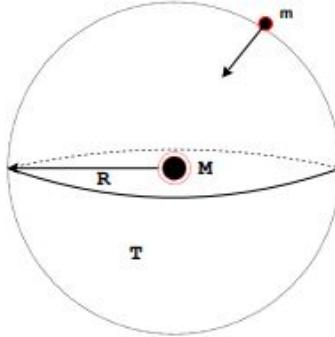

Figure 1. Our system consists of a source mass M and a "boundary" which is a data storing surface such as a holographic screen. T is the temperature of the bounding surface arising from the even distribution of the total energy E of the mass m as N bits of information as it approaches the holographic boundary.

² see [36]

3. Effect on Total Energy

Due to the thermodynamic nature of our system, the total energy changes by the internal energy (U) and the fluctuation energy as we show now. The internal energy is given by

$$U = TS \quad (8)$$

where T is the temperature of the boundary and S is given by C_D . To find the degree of fluctuation in our system we expand the disorder D about its equilibrium position x_0^μ

$$D = D_0 + \frac{\partial D}{\partial x^\mu} \Big|_0 dx^\mu + \frac{1}{2} \frac{\partial^2 D}{\partial x^\mu \partial x^\nu} \Big|_0 dx^\mu dx^\nu + \dots \quad (9)$$

Note that here μ varies from 0 to 3 on 4D spacetime. Since x_0^μ is the equilibrium point for D , we have

$$\frac{\partial D}{\partial x^\mu} \Big|_0 = 0 \quad (10)$$

Thus, in second order we have:

$$\Delta D = D - D_0 = \frac{1}{2} \frac{\partial^2 D}{\partial x^\mu \partial x^\nu} \Big|_0 dx^\mu dx^\nu \quad (11)$$

The hessian $h_{\mu\nu}$ which captures the degree of "fluctuation" in our thermodynamic system is given as

$$h_{\mu\nu} = \partial_\mu \partial_\nu D \quad (12)$$

Another important dimensionless quantity (which can be used to define the "length" of fluctuation) is defined as

$$\tilde{h}_{\mu\nu} = \frac{A}{\pi} h_{\mu\nu} \quad (13)$$

where A is the surface area of the boundary. dl^2 is the length squared of fluctuation given by

$$dl^2 = \frac{1}{2} \tilde{h}_{\mu\nu} dx^\mu dx^\nu \quad (14)$$

We thus define the fluctuation energy as

$$\left(\frac{dl}{d\tau} \right)^2 = \frac{1}{2} \tilde{h}_{\mu\nu} d\dot{x}^\mu d\dot{x}^\nu \quad (15)$$

This thermodynamic expansion of the total energy comes at the expense of extending the 4D spacetime to 5D spacetime such that the non-zero metric elements are given by

$$g_{00} = 1, g_{11} = g_{22} = g_{33} = g_{04} = g_{40} = -1 \quad (16)$$

The fifth element of the "five-momentum" p^μ is defined as

$$p^4 = U + \frac{dl}{d\tau} \quad (17)$$

4. Static Mass and Spherically Symmetric Solution

The total degrees of freedom on the boundary is

$$N = \frac{A}{l_p^2} = \frac{4\pi r^2}{l_p^2} \quad (18)$$

Thus

$$U = \frac{Mp^0}{r} \quad (19)$$

for $\tilde{h}_{\mu\nu}$, only 11 component survives. Thus

$$\tilde{h}_{11} = \frac{4M}{r} \quad (20)$$

Hence the fluctuation energy in our thermodynamic system is

$$\left(\frac{dl}{d\tau} \right)^2 = \frac{2M}{r} \dot{r}^2 \quad (21)$$

Thus

$$\left(\frac{dl}{d\tau} \right) = \sqrt{\frac{2M}{r}} \dot{r} \quad (22)$$

So we get

$$dx^4 = \frac{M}{r} dt + \sqrt{\frac{2M}{r}} dr \quad (23)$$

The spacetime interval is given as

$$ds^2 = g_{\mu\nu} dx^\mu dx^\nu \quad (24)$$

where $g_{\mu\nu}$ is the fixed 5D background spacetime. Hence in the spherical coordinates, we get the spacetime interval as

$$ds^2 = dt^2 - dr^2 - r^2(d\theta^2 + \sin^2\theta d\phi^2) - \frac{2M}{r} dt^2 - 2\sqrt{\frac{2M}{r}} dt dr \quad (25)$$

Eq.(25) is the Gullstrand-Painleve metric and a coordinate transformation converts it to the well-known Schwarzschild metric given as

$$ds^2 = \left(1 - \frac{2M}{r}\right) dt^2 - \left(1 - \frac{2M}{r}\right)^{-1} dr^2 - r^2(d\theta^2 + \sin^2\theta d\phi^2) \quad (26)$$

5. Quantum Focusing Conjecture

Using the Quantum Focusing Conjecture(QFC)[31], we can show that the second derivative of the radius of a null boundary which respects the null energy condition(NEC) is non-negative. In this section, we first review the formulation of QFC.

5.1. Generalised Entropy for Cauchy-splitting surfaces

Generalized entropy was originally defined in [37] in asymptotically flat space as the area A of all black hole horizons, plus the entropy of matter outside the black holes

$$S_{gen} = S_{out} + \frac{A}{4G\hbar} \quad (27)$$

A rigorous definition of S_{out} can be given as the von Neumann entropy of the quantum state of the exterior of the horizon

$$S_{out} = -tr\rho_{out}ln\rho_{out} \quad (28)$$

The GSL was introduced to keep the second law of thermodynamics intact when matter entropy is lost in a black hole. Bekenstein conjectured that GSL [37] holds: that the area increase of the black hole compensates for the lost matter entropy so that the generalized entropy does not decrease. The notion of generalized entropy can be extended beyond the context of causal horizons [31]. Let E be a spacelike codimension-2 surface that splits a Cauchy surface C into two portions. By choosing any one of the two sides arbitrarily, we can define an entropy restricted to one side of C as S_{out} .

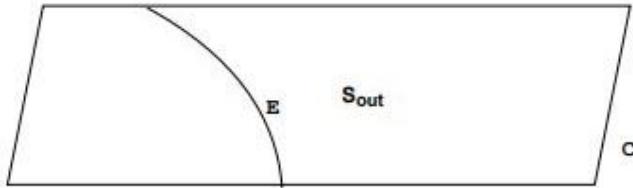

Figure 2. A Cauchy surface C is divided into two parts by a surface E . S_{out} is defined as entropy restricted to one side of splitting surface E

5.2. Quantum Focusing Conjecture

It conjectures [31] that the quantum expansion Θ , where Θ is given by

$$\Theta = \theta + \frac{4G\hbar}{\mathcal{A}} S'_{out} \quad (29)$$

(θ is the classical expansion and \mathcal{A} is the width of null congruence along its generator), cannot increase along any congruence, which is valid for quantum states too

$$\frac{d\Theta}{d\lambda} \leq 0 \quad (30)$$

where λ is an affine parameter. The evolution of the expansion θ along congruence is determined by the Raychaudhuri equation:

$$\frac{d\theta}{d\lambda} = -\frac{\theta^2}{2} - \sigma_{ab}\sigma^{ab} - R_{ab}k^a k^b : \quad (31)$$

where R_{ab} is the Ricci tensor, σ_{ab} is the shear and k^a is the (null) tangent vector to the congruence. This gives QFC as

$$0 \geq \Theta' = \theta' + \frac{4G\hbar}{\mathcal{A}} (S''_{out} - S'_{out}\theta) = -\frac{1}{2}\theta^2 - \zeta^2 - 8\pi G\langle T_{kk} \rangle + \frac{4G\hbar}{\mathcal{A}} (S''_{out} - S'_{out}\theta) \quad (32)$$

ζ is shear. The special choice of congruence for $\theta = \zeta = 0$, gives the Quantum Null Energy Condition (QNEC)

$$\langle T_{kk} \rangle \geq \frac{\hbar}{2\pi\mathcal{A}} S''_{out} \quad (33)$$

The entropy S_{out} which refers to the entropy on a spacelike Cauchy surface can also be alternatively seen as the entropy of the state restricted to the part of null surface N [31]. The stress tensor T_{ab} and entanglement entropy S_{out} is related to relative entropy $S(\rho||\rho_o)$ on a null surface by

$$\frac{2\pi\mathcal{A}}{\hbar} T_{kk} - S''_{out} = S''(\rho||\rho_o) \quad (34)$$

where $T_{kk} = T_{ab}k^a k^b$, k^a is a null vector, i.e, it satisfies $g_{\mu\nu}k^\mu k^\nu = 0$. ρ is an arbitrary state and ρ_o is the vacuum state.

6. Relative Entropy and Bekenstein Bound

The Bekenstein bound is given as

$$S \leq \lambda E R \quad (35)$$

where λ is a constant, R is the size of the system, E is the total energy. Casini[38] showed that the above bound can be written in the form

$$S_V \leq K_V \quad (36)$$

where S_V is a localized entropy and K_V is a localized energy. Using $K = -\log\rho_V^0 - \log(\text{tr}e^{-K})$ and $\text{tr}\rho_V = \text{tr}\rho_V^0 = 1$, this can be written as

$$\text{tr}(\rho_V \log \rho_V) - \text{tr}(\rho_V \log \rho_V^0) \quad (37)$$

This is simply the statement of the positivity of the relative entropy $S(\rho_V||\rho_V^0)$ between the state ρ_V and the vacuum state ρ_V^0 and thus the bound holds. Suppose the size of a system is L and the radius of the boundary R , in the limit when the system is far enough from the boundary such as at the center, $R \gtrsim L$ then Eq.(36) reduces to Eq.(35). We will use this limit in the next section.

7. Towards Accelerated Expansion

Consider a surface Σ on a stationary null surface N (a Rindler horizon) and its deformation along N toward the future, so that the deformation vector k^a is future-directed and the outside is chosen to be the side towards which k^a points (see Fig.1). A measure of distinguishability between any two states of an arbitrary quantum system is relative entropy. It is a quantity of particular significance in quantum information theory. Its illuminating use in the gravitational context was put by Casini[38]. On the states restricted to this causal horizon, the relative entropy is given by

$$S''(\rho||\rho^{(0)}) = \frac{2\pi\mathcal{A}}{\hbar} \langle T_{kk} \rangle - S''_{out} \quad (38)$$

At late times on this causal horizon, we take the matter entropy S_{out} to stop evolving such that $S'_{out} = 0$. This essentially requires the quantum expansion $\Theta \rightarrow 0$ on the causal horizon since for the stationary causal horizon, the classical expansion vanishes, $\theta = 0$. Using the QNEC, we can now write Eq.(38) as an inequality given by

$$S''(\rho||\rho^{(0)}) > 0 \quad (39)$$

The relative entropy can be written as the statement of the Bekenstein Bound as

$$S(\rho || \rho^{(0)}) = K_v - S_v \quad (40)$$

where K_v is a localized energy and $S_v = S_{out} - S_{out}^{(0)}$, $S_{out}^{(0)}$ being vacuum entropy. Since $S'_{out} = 0$ and the vacuum entropy is independent of the affine parameter λ (the vacuum state on the pencil is invariant under translations in the affine parameter), Eq.(39) takes the form

$$K''_v > 0 \quad (41)$$

Since, in the local neighborhood of any point p , we can define a Rindler horizon, this result holds for the entire spacetime points. We now apply this result to the universe as a whole. Since the arguments presented hold locally, the extension to the entire universe requires a global existence of a causal horizon. This can be circumvented by considering a universe-antiuniverse pair, in which case, the junction ($t = 0$) of the universe-antiuniverse pair which causally disconnects the pair (see Fig.2) naturally serves as the stationary causal horizon and the result of Eq.(41) can be extended globally. This is similar to the existence of the Unruh effect for a local Rindler horizon to that of the Hawking effect for a global event horizon of a black hole. The affine parameter λ can now be taken to be the cosmic time t and the total energy E of the universe is constant. Take the radius of the boundary of the universe to be R (with R possibly infinity), such that the bulk of size L always satisfies $L \ll R$. In this limit, $K_v \equiv 2\pi ER$ and we can finally write Eq.(41) as

$$\dot{R} > 0 \quad (42)$$

Thus, the boundary of the universe expands in an accelerated manner. It should be noted that the sign of S''_{out} can be anything, including negative, but at late times, the matter entropy stops evolving such that the quantum expansion tends to zero, $\Theta \rightarrow 0$, and in this case, the expansion of the universe is accelerating without need of any external agent, all by itself!

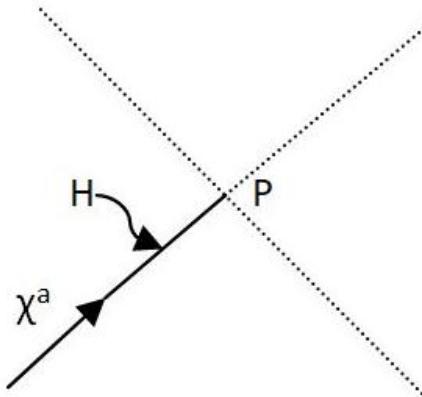

Figure 3. A Rindler horizon shown by a bold line of a 2-surface element P . To the right Rindler wedge in the region $z > |t|$ with Cauchy surface the spatial half-plane V defined by $z > 0$ at $t = 0$, we can apply Casini's idea.

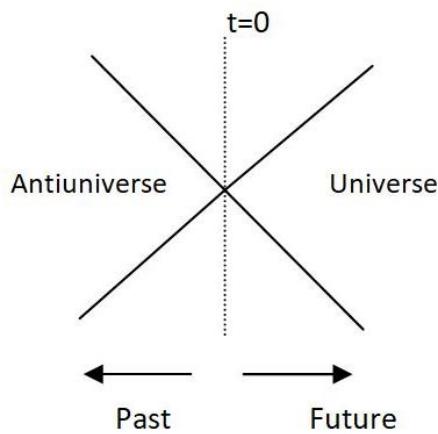

Figure 4. A universe-antiuniverse pair. The surface at $t = 0$ acts as a causal horizon.

8. Conclusion

This approach of describing gravity as information leads to a very important question of whether or not gravity is a fundamental force as popularly seen. We think the way gravity affects time strongly suggests that gravity can not be a force in the usual sense. Of course, we have to make an additional assumption that the degrees of freedom follow the holographic principle and scales as the area rather than the volume of space but this assumption is very robust in itself looking at black hole physics and gauge/gravity duality. The other important result we argued is: if we look at from a quantum perspective, the most natural way in which the universe can be created is in pairs whose time flow is oppositely related. This suggests the idea of the creation of a universe-antiuniverse pair. Assuming the validity of this hypothesis, in this paper, we showed that the universe at late times expand in an accelerated manner. This does not require any form of dark energy as used in the standard cosmological model of Λ CDM.
