Abstract: The wild grapevine, *Vitis vinifera* subsp. *sylvestris* grows naturally throughout the northern hemisphere, including the Mediterranean region. Wild grapevines were also observed sporadically across the southern Levant and has so far been considered as non-native feral plant. Nevertheless, no formal characterization was conducted for wild grapevines in this region, thus its taxonomical assignment remains elusive. Here we describe the morphological, anatomical, and ecological characterization of wild grapevines that is a naturally thriving plant in Israel and conclude that *Vitis vinifera* subsp. *sylvestris* is a native plant in this region which marks the southern border of its distribution range. These findings, combined with the recently-published genetic evidence for these populations significantly advance our understanding of the species' ecology and persistence under climate change.

Keywords: Sylvestris; *Vitis*; wild grapevine; *Vitis vinifera* subsp. *sylvestris*; species persistence

1. Introduction

The *Vitaceae* family includes mostly shrubs and woody lianas that climb using leaf-opposed tendrils. Most grape cultivars belong to the *Vitis* genus, consisting of 83 inter-fertile species [1] that exist primarily in the Northern Hemisphere including North America and East Asia. The Eurasian species of common grapevine, *Vitis vinifera* var. *sylvestris* Willd. [2] (hereafter Sylvestris) is the best-known as it is the ancestor of most cultivated grapes grown today [3–5]. The cultivated form *V. vinifera* ssp. *sativa* (hereafter Sativa) is one of the most important perennial crops which is cultivated across 7.3 hectares around the world [6]. The distinction between these two subspecies rely largely on the differences in the reproductive organs morphology, namely while the wild grapevine is dioecious, Sativa is a hermaphrodite [5,7,8].

Sylvestris was naturally grown abundantly in Europe until the mid-19th century, when penetration of pests and pathogens from North America, including phylloxera, powdery and downy mildews, caused a decrease in wild grapevine populations [8]. Later, the accelerating urbanization processes and extensive anthropogenic land use dramatically damaged the natural habitats of Sylvestris populations, reducing its distribution range and endangering the species persistence [9,10]. While Sylvestris populations were shrinking, Sativa was flourishing throughout Europe and Eastern Mediterranean region by the end of the 19th century, “cultivated everywhere in numerous varieties, but nowhere strictly spontaneous” [11].

The Southern Levant was considered as region beyond the distribution range of Sylvestris, thus early studies of Israeli vegetation during the 20th century considered all grapevine plants as cultivars (Sativa) and the species was not included in the local wild flora records until 2004 [12]. The first

indications for *Sylvastris* in the Southern Levant region was in 1994 based on surveys in the Upper Galilee region; along the banks of Jordan River [13,14]. Nevertheless, the available records of these surveys lack the necessary description and exact location of the observed plants, therefore, generally, grapevines observed in the wilds in Israel were considered feral populations with no clear support.

Over the years, more evidence for native Southern Levantine *Sylvestris* have accumulated. Archaeobotanical pips and wood of *Sylvestris* plants were discovered in the region from Lower Paleolithic Gesher Benot Ya'akov (780,000 BP) and from Upper Palaeolithic Ohalo II (23,000 BP) archaeological sites [15–18]. These archaeological sites are located around the area of Sea of Galilee and Jordan River, in high geographic proximity to the populations observed in 1995 survey.

A more recent comprehensive survey of grapevines in Israel discovered new populations of hermaphrodite and dioecious plants [19]. Genetic analysis with SSR markers and morphological characterization of the collection indicated that the hermaphrodite accessions were clearly separated from the dioecious groups, having additional wild grapevine phenotypes (leaf, bunch and berry shape, etc.). Moreover, dioecious *Sylvestris* accessions were further split between two distinct subgroups in accordance with ecogeographic divergence. These populations, occurring primarily along the main streams in the Upper Galilee region and around the Sea of Galilee, mark the southern edge of the distribution range of *Sylvestris* [20].

Deeper analyses of these accessions using whole genome sequencing data further supported the previous observations that *Sylvestris* has grown naturally in the Southern Levant for Millennia [21]. In fact, the *Sylvestris* accessions were identified as progenitors of domesticated indigenous varieties from the Levant with genetic contribution to some of the European varieties [21,22]. These conclusions were further supported in a recent comprehensive genomic study of more than 3,500 accessions which provided an unequivocal evidence for the contribution of Southern Levantine *Sylvestris* populations to domesticated grapevine around the world [23]. The *Sylvestris* populations from Israel (E1) were identified as the genetic source table-grape group (CG1) [23]. This group later genetically contributed to most known wine grape varieties used in modern times worldwide.

Despite the number of studies and evidence for the thrive of *Sylvestris* populations in Israel, no conclusive support and clear definition has been provided so far. This gap opens room for skepticism with implications on the interpretation of genomic studies of domestication, ecology and evolution. Here, we provide a comprehensive morpho-anatomical characterization of *Sylvestris* populations representing the two main subgroups in Israel including a deep characterization of male and female flowers, the distribution dynamics of male and female individuals in each region, and the natural regeneration by germination. The results clearly affirm that the populations inspected are truly assigned to the protologue and type specimens of *Vitis vinifera* subsp. *sylvestris*.

2. Materials and Methods

Plant material and research area: Sampling was carried out during the spring (May 2022) in Northern Israel where stable populations of *Sylvestris* were previously observed [20]. Forty-six *Sylvestris* accessions were collected from the Banias River in the Upper Galilee (33°12'12.3"N 35°38'27.6"E), and the Beit Tsaida site located next to the Sea of Galilee (32°53'09.2"N 35°38'34.6"E), from an area of about 8000 m² in each site (Figure 1). For each accession, twigs with young and mature leaves, as well as flowers were collected. A subsample of each accession was dried and prepared for Herbaria deposition, and remaining parts were fixed and stored in FAA solution (formaldehyde: acetic acid: 70% ethanol, 1:1:20) for histomorphological inspection (samples are held in the Ariel University). The exsiccata of all accessions were deposited at Tel Aviv University (voucher specimen numbers from TELA4443 to TELA4450).

Figure 1. The study sampling sites (a) Map of the northern part of Israel. The black squares mark two study areas on the map (b) An aerial photo of Baniyas area (c) An aerial photo of the Beit Tsaida area. Blue and red dots represent male and female accessions, respectively.

Morphological characterization

Leaf: The leaf morphology was examined in dry herbarium specimens. We measured the length of the petiole, length and width of the leaves in their greatest extension, and calculated the ratio between length and width and the length ratios of the blade to the petiole. We noted the shade difference between the abaxial and adaxial sides of the leaf lamina, determining whether leaves are concolourous or discolourous. We described the leaf form according to the glossary in Kafkafi [24].

Seed and berry: Approximately 60 seeds and 100 berries from each site were used for morphological characterization and statistics. The metric measurements (Berry diameter, seed length and width) were taken using a Sparkfun electronics digital calliper (0-15 mm), and the data presented is the range of sizes (min-max). In addition, morphological descriptors (OIV) [25] were used to describe the morphological traits of seeds and berries.

Flower: Male and female flowers were placed on a microscope glass slide wrapped or unwrapped with black paper and illuminated with white LED light. Images were captured with a Nikon SMZ25 stereo-microscope (Nikon Ltd., Japan) equipped with a camera (Nikon DS-Ri2). Sixty digital photo-micrographs (resolution: 4908×3264 pixels), with each step about 50 μ m, were taken at different focal planes and compiled to a single image using ND2-NIS elements software with an extended depth of focus (EDF) patch (Nikon Instruments, Japan). Images were then transformed into a single high-quality focused image using the dedicated software.

Pollen: Dried anthers with pollen grains were coated with gold using sputter machine (Quorum Q-150T ES). The prepared samples were then imaged using FE-SEM (Tescan Ultra - High Resolution MAIA 3). Beam voltage 1.0 kV and SE detector were used for samples.

Tissue histology: Tissue samples of male and female flowers were fixed in FAA (formaldehyde: acetic acid: 70% ethanol, 1:1:20), embedded in paraplast, sectioned at 12 micron thickness with a rotary microtome (SLEE medical GmbH, Germany) and stained with safranin-alcian blue stain [26]. The slides were photographed under Olympus SZX7 stereo-microscope equipped with a camera (Pixelink USB 3.0, Canada) and using PixelINK Capture program.

3. Results

Sylvestris growth habit in wild habitats: In this study, we focused on the two sites where stable and large grapevine populations were previously reported [20]; the northern site at the Baniyas River, and the southern site at Beit Tsaida (Figure 1). Both sites are located in protected natural reserves (Baniyas and Majrase, respectively). Sampling was performed randomly along the water streams

where grapevine grows in each site, thus a total of 46 accessions were sampled of which 32 are from Beit Tsaida, and 14 from the Banias River.

Sampling was performed during the spring when plants were in full blossom which enables to identify developing pistils and stamens in dioecious (unisexual plants) or monoecious plants. All *vitis* plants at both sampling sites were dioicous, supporting their identification as true *Sylvestris*. The ratio between male and female plants is close to 1, with a slightly higher number of male accessions (Table 1). This finding strengthens our assumption that the examined populations are wild, with no bias toward the fructiferous female form [27].

Table 1. Summary of grapevine collection in the research areas.

Gender/Locality	Beit Tseida		Banias	
	N	Percentage of total	N	Percentage of total
Female plant	15	46.9%	7	50%
Male plant	17	53.1%	7	50%
Ratio	0.88		1	

Growth habit varied between male and female grapevines at both locations. Male grapevines were taller and tended to climb to the tops of trees, while female grapevines were shorter and tended to prostrate in a tangle of low vegetation (Figure 2a, b). The male grapevines were characterized by multiple and densely packed flower clusters, usually located near the top of the vine (Figure 2b), and females produced fewer and smaller flower clusters (Figure 2c) which were located lower along the stem. These male climbing habit may be attributed to wind-pollination strategy [28] and the low stature of the female may be required to structurally support the heavy bunches of fruits. The sexual dimorphism observed in plants height and inflorescence position seem adaptive to the natural habitat.

Figure 2. Growth habits of *Sylvestris* plants in Northern Israel. (a) Male grapevine climbs on the tree in Beit Tseida, (b) female grapevine by the side of the road in Banias (c) male inflorescence, d) female inflorescence.

In our current survey, grapevines were growing in deep uncultivated soils very close to flowing sweet water, as was previously reported [20]. Male and female plants were spread randomly. In both sites, the wild grapevines grow in proximity to fig trees (*Ficus carica*), plane trees (*Platanus orientalis*), and holy raspberries (*Rubus sanguineus*). This plant community is typical to water-rich habitats along the Mediterranean basin. Interestingly, the observed *Sylvestris* female plants tended to grow between the spiny holy raspberry plants which provide protection from herbivores that are abundant in these regions including the wild boar (*Sus scrofa*) and gazell (*Gazella gazella*) which commonly feed from grapevine shoots and leaves. On the other hand, male *Sylvestris* plants tend to climb higher trees as means of support, avoidance of both herbivores, and competition for sunlight.

Overall, the observed populations at both sites has a distinctive appearance with a significant polymorphism in leaves, and clusters of small, greenish-yellow flowers developed into black berries. Its growth habit and woody stem make it a hardy plant providing cover and habitat for various animals in its natural environment [29,30].

3.2. Morphology

Leaf morphology: Leaf shape and morphology show a high polymorphism, ranging from reniform with weak lobation to cordate with pronounced lobation. No significant correlation between leaf shape and sampling location was observed and length-width blade ratios (t-test, p-value>0.05)) (Table 2). The blade-petiole length ratio was higher in Beit Tseida (t-test, p-value<0.0001). The dorsal surface of the leaves from Banias was found to be hairy in contrast to leaves from Beit Tseida. This results in a shade contrast, causing the leaves in the Banias populations to be discolored, while the Beth Tseida populations have concolor leaves.

Table 2. Comparison of the main morphological features of *Sylvestris*. Terminology is according to [31], and to the OIV descriptors ([32]) for the berries and seeds.

	Beit Tseida	Banias
Abaxial/adaxial leaf color contrast	Concolor	discolor
Blade \ petiole length ratio	1.72 (sd±0.92)	1.09 (sd±0.3)
Blade shape	not constant	trilobate
Blade size ratio	0.8 (sd±0.11)	0.76 (sd±0.093)
Color of berry skin (OIV 225)	blue black (6)#	blue black (6) #
Berry shape (OIV 223)	globose (2)#	globose (2) #
Berry diameter (min-max) [mm]	10.04 (sd±0.90)	11.34 (sd±0.97)
Seed shape	Ellipsoid	ellipsoid

Seed length (OIV 242)	very short (1) #	very short (1) #
Seed length (min-max) [mm]	5.38 (sd±0.45)	5.10 (sd±0.42)
Seed width (min-max) [mm]	3.66 (sd±0.29)	3.68 (sd±0.23)

numbers indicate OIV description parameters.

Berry and seed morphology: Growing conditions have a dramatic effect on the number and size of grapes berries and seeds. To obtain healthy, large berries and seeds for inspection and characterization cuttings were sampled from plants at both sites and were grown under optimal conditions at the experimental vineyard station in Ariel University [33]. Figure 3a shows well grown and dense fruit bunches when grown under irrigation, while Figure 3b shows the sporadic of Sylvestris bunches grown in the wild. A broad range of polymorphism in cluster shapes was observed among samples, yet most of them had sparse clusters of tiny, typically black berries, that usually contain 2-3 seeds (Figure 3c). The berries diameter was found to be significantly different (p-value < 0.001) between the populations when Baniyas Sylvestris berries being bigger than those of Beit Tseida (Table 2). In both populations, the berry’s skin is thin, and the pulp is juicy and sweet with high acid levels, but lower than those found for European Sylvestris grapes [19]. The seeds length was differed significantly between sampling sites (t-test, p-value < 0.001), where the seeds from Beit Tsaida were larger (mean = 5.38, sd = 0.45)(Table 2). These values correspond to Sylvestris varieties and were previously recorded [34,35].

Figure 3. Berry and seeds morphological traits of Sylvestris from Northern Israel. Female grapevine bunches (a) from collection vineyard (b) from the wilds (Beit Tsaida). (c) A whole grape berry next to a sectioned berry (N22). (d) Ventral (on the right) and dorsal (on the left) sides of seeds (N189) on 1 mm squared paper.

Flower morphology: The main feature that distinguishes between wild and domesticated grapevine is the flower and more specifically the reproductive organs. The flowers of the wild grapevine are small and greenish-yellow and are arranged in panicles. The individual flowers have a diameter of around 5 mm and contain five petals fused at the base. The flowering occurs in the month of May, giving rise to fruit on female individuals later in the summer (August). The structure

of the male flower is distinctly different from that of the female flower (Figure 4). The female flower includes an ovary and reflexed rudimentary/atrophied stamens that angle downwards, while the male flower displays upright stamens and a reduced pistil without style or stigma and an rudimentary/atrophied ovary at the base. These features are clearly distinctive to *Vitis sylvestris* plants, while the *Sativa* forms, also found occasionally feral, all have an hermaphrodite phenotype.

The histological sections of the female grapevine flower show a single ovary (Figure 4c), a style, and a stigma, which comprise the pistil. The ovary is located at the base of the flower and contains ovules that will eventually develop into seeds if fertilized by pollen (Figure 4c). In contrast, the male grapevine flower sampled at the same location had a different structure which consists of an atrophied ovary and stamens that are arranged in a tight cluster at the base of the flower. The stamens produce and release pollen grains from wind and/or insects to the female flowers, allowing for fertilization and fruit production [36].

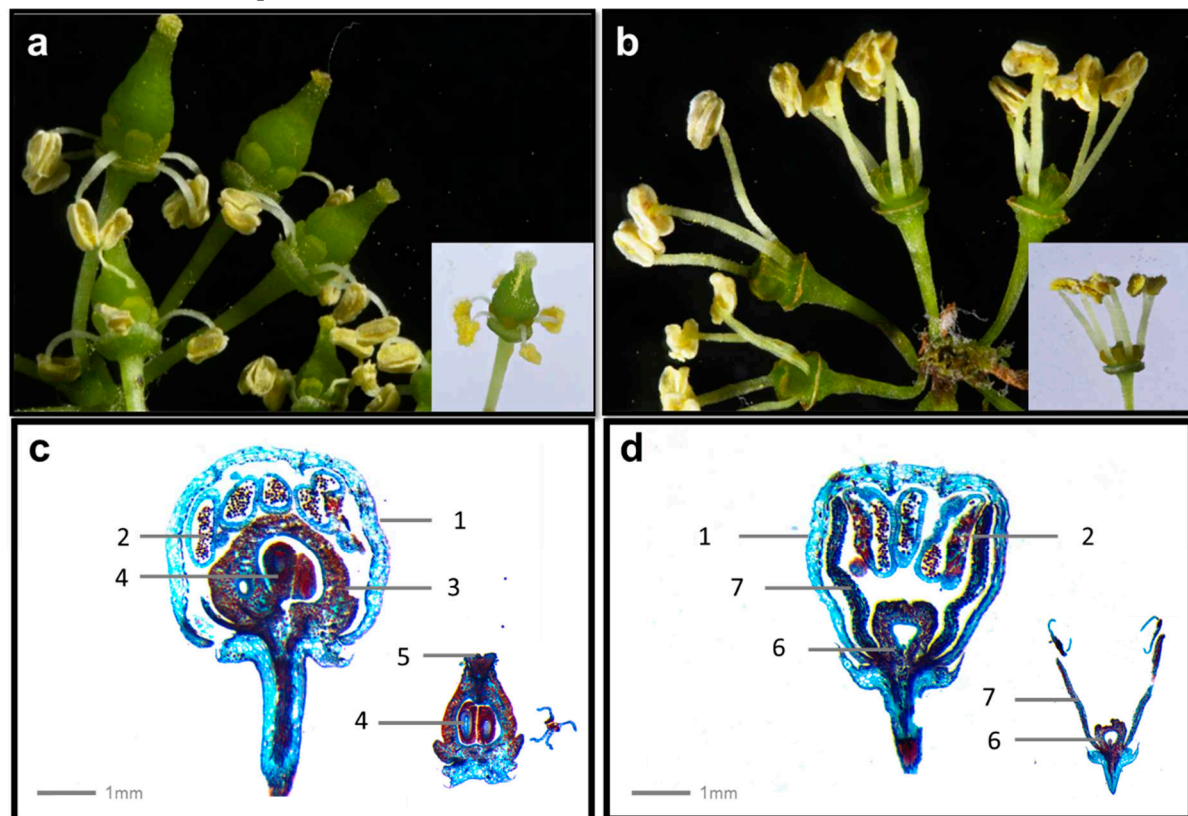

Figure 4. Female and male flowers of samples and their histology sections. (a) Female and male (b) specimens at flowering. (c) Histological sections of closed and open (on the low right side) female and male (d) flowers. Parts of the flower: 1- Petal, 2-Anther, 3-Ovary, 4- Ovules, 5-Stigma 6- Atrophied ovary remnant, 7-Anther filament.

Pollen grains morphology: A scanning electron microscope (SEM) was utilized to image the pollen of *Sylvestris* accessions sampled at experimental vineyard (Figure 5). In the male flowers, the pollen grains exhibited tricolpate morphology (with three furrows), and were ellipsoid in shape. In the female flowers, the pollen grains were inaperturate and spheroidal in shape (Figure 5). Additionally, pollen grains found on anthers in female flowers appeared collapsed or exhausted, and potent in male flowers further supporting deioicy. The morphological description of pollen grains in grapevines is consistent with previous findings on the differences between sterile and fertile pollen grains in *Sylvestris* [37,38].

Figure 5. SEM images of pollen grains produced by female (a) and male (b) flowers of *Vitis vinifera* ssp. *sylvestris* inside the anther. The scale bar is 50 µm enlarged single pollen grains are represented on the top-right of each image.

Natural seed germination: We conducted a thorough survey of the Sylvestris habitats in the wild in search for natural germination of seedlings. In the Baniyas area, we found five seedlings, all beneath female plants (Figure 6a). This germination habit was abundant indicarting its success under the ecological conditions of this specific natural habitat. The young plantlets were carefully removed from the soil with their seed hulks (Figure 6c,d). The grapevine seeds were clearly identified despite being slightly damaged and soiled. To the best of our knowledge, this is the first time that natural germination of Sylvestris in its natural habitat has been recorded. These natural germinations at a natural habitat provide a strong evidence for the authenticity and persistence as a stable population of Sylvestris as an indigenous plant in Israel. Due to the growth habit of Sylvestris inside a dense bush of spiny raspberry plants we failed to identify young seedlings at the Beit Tseida area.

Figure 6. *Vitis vinifera* ssp. *sylvestris*'s generation. (a,b) Germinated young plants found in the Baniyas area under female vines and their seeds (c-ventral side, d-dorsal side) which were pulled from the ground.

4. Conclusions

Previously, grapevine found growing in the wilds at the northern part of Israel, were considered to be feral sativa plants, and there was no confidence as to the occurrence of *Vitis sylvestris* in Israel. The reasons were the lack of a comprehensive survey, and the minimal description of this population by the surveyors, giving only brief and amorphous descriptions [13,14]. Here, we systematically described the habitats, growth habits, morphology and anatomy of widely spread wild grapevine populations growing in two habitats. All of the above findings, including the dioecious nature of the wild grapevine plants, the sexual dimorphism between male and female plants, the characteristic traits of the flower, pollen, berry, and seed structure, and the natural regeneration of the population from seeds, together with our previous genomic findings showing clear separation of these populations from feral *Sativa* accessions, all lead us to the conclusion that natural wild grapevine populations grow in Israel. Our results indicate that wild grapevine occurs in nature reserves located within the region of its ancient area of appearance during the Pleistocene [39].

The high importance of this botanical definition, clearing up any previous uncertainty as to the definition of these populations as *Sylvestris* is due to the emerging importance of these wild populations as representatives of the core population from which the cultivated grapevine was first domesticated circa 11,000 years ago [23]. These facts also emphasize the significance of conservation of the environmental conditions and biodiversity of the Sea of Galilee and the forest habitats in the Upper Galilee, as the main habitats of this important populations.

In sum, the evidences presented here confidently support the persistence of the wild grape species in the Israeli flora, moving the southern edge of its global distribution. As a result, Israel can be confidently added to the native distribution of *Vitis vinifera*, and this plant included in the Flora Palaestina.
