Abstract: In mammals, the role of interleukin-18 (IL-18) in the immune response is to drive inflammatory and, normally therefore, anti-viral responses. IL-18 also shows promise as a vaccine adjuvant in mammals. Chicken IL-18 (chIL-18) has been cloned. The aim of this study was to investigate the potential of chIL-18 to act as a vaccine adjuvant in the context of a live recombinant Fowlpox virus vaccine (fpIBD1) against Infectious bursal disease virus (IBDV). fpIBD1 protects against mortality, but not against damage to the bursa of Fabricius caused by IBDV infection. The Fowlpox virus genome itself contains several candidate immunomodulatory genes, including potential IL-18 binding proteins (IL-18bp). We have knocked out (Δ) the potential IL-18bp genes in fpIBD1 and inserted ($::$) the cDNA encoding chIL-18 into fpIBD1 in the non-essential ORF030, generating five new viral constructs –fpIBD1::chIL-18, fpIBD1 Δ ORF073, fpIBD1 Δ ORF073::chIL-18, fpIBD1 Δ ORF214 and fpIBD1 Δ ORF214::chIL-18. The subsequent protection from challenge with virulent IBDV, as measured by viral load and bursal damage, given by these altered fpIBD1 strains, was compared to that given by the original fpIBD1. The results show that chIL-18 can act as a vaccine adjuvant, giving complete protection against challenge, with no detectable virus or damage in the bursa of Fabricius.

Keywords: chicken interleukin-18; vaccine adjuvant; recombinant Fowlpox virus FP9; fpIBD1

1. Introduction

Infectious bursal disease (IBD) was first recognised in Gumboro, Delaware, USA in 1962 [1], hence its alternative name, Gumboro disease. IBD known to cause high economic losses for poultry industry throughout the world by its high morbidity and a mortality rates in infected chickens [2]. Before 1980s, IBD was well controlled by vaccination, however, by the end of 1980s many vaccination failures were reported worldwide, due to the emergence of variant and, later on, very virulent strains of IBD virus (IBDV). The new strains of IBDV called “variant” strains in the USA [3], and “hypervirulent” or “very virulent” IBDV (vvIBDV) strains in Europe [4].

Recombinant Fowlpox viruses have been used as a vector to express targeted genes from many avian pathogens, such as Newcastle disease virus [5,6], Avian influenza virus [7], Turkey rhinotracheitis virus [8], Marek's disease virus [9] and IBDV [10].

IBDV is a Birnavirus, characterised by having a bisegmented double stranded RNA genome [2]. IBDV encodes five proteins in which VP2 is the capsid protein. VP2 is known as the host-protective antigen [11]; hence it has been selected to produce new recombinant vaccines. VP2 was expressed in the FP9 strain of Fowlpox virus [12] to generate a recombinant vaccine, fpIBD1 [10]. In previous study, fpIBD1 was able to provide significant levels of protection against the challenge with IBDV. However, this protection was mainly against mortality, but not against damage that occurred by

IBDV to the bursa of Fabricius [10]. In addition, the protection of the fpIBD1 vaccine was dependent on other factors such as the titre of IBDV and also the difference of the major histocompatibility complex (MHC)-haplotype of the specific pathogens free (SPF) chickens used in the experiment [13].

Interleukin-18 (IL-18) is well known as a pro-inflammatory cytokine, as well as an interferon-gamma-inducing factor (IGIF), plays an important role in the development of T-helper type 1 (Th1) cells, which drive cell-mediated immune responses. As IL-18 is an inducer for Th1 response, it therefore seemed logical to investigate the efficacy of IL-18 as a vaccine adjuvant. Chicken IL-18 (chIL-18), originally identified in an EST database, was cloned and expressed [14].

It was claimed that the ORF FPV073 (in the Fowlpox virus genome) was a homologue of human IL-18bp and an orthologue of IL-18bps from *Molluscum contagiosum* virus, Swinepox virus and *Vaccinia* virus [15]. It was later shown that ORF FPV214 is more likely to be the correct assignment [12]. Thus FPV214, but not FPV073, aligns with a conserved motif (97YWxxxxxFIEHL108 in humans) in the other IL-18bps. In contrast, FPV073 contains a GxGxxG nucleotide-binding motif and shows highest similarity to a tyrosine protein kinase. It seemed logical to delete IL-18bp from vector containing chIL-18 as an adjuvant. Therefore, both Fowlpox virus ORFs 073 and 214 were knocked-out, separately, from fpIBD1. ChIL-18 was then inserted into the non-essential [16] PC-1 gene (ORF FPV030) of fpIBD1. Then the protection provided by these new vaccines was compared to the original fpIBD1, in terms of clinical signs, bursal damage and viral loads in the bursa of Fabricius following challenge with virulent IBDV.

2. Materials and Methods

2.1. Chickens

Outbred Rhode Island Red (RIR) chickens were used in all animal experiments. The chickens were bred at the Institute for Animal Health (IAH), were free from specific pathogens including IBDV, free of maternal IBDV antibodies and maintained in isolation in wire-floored cages with free access to food and water.

All animal experiments were carried out in the experimental animal house (EAH) at the IAH. All procedures were carried out according to UK Home Office guidelines for animal welfare.

2.2. Viruses

fpIBD1 is a recombinant vaccine originated from the Fowlpox virus FP9 [10]. fpIBD1 is expressing the VP2 protein of the IBDV F52/70 that has been inserted in the BglII insertion site in the ORF FPV002 as a β -galactosidase fusion protein under the control of the early/late promoter of the *Vaccinia* virus p7.5 (Figure 1). CEF were prepared from 9-10-day-old embryonated eggs. chicken embryo fibroblast (CEF) cells were provided in either petri dishes or different sizes of T flasks, fpIBD1 was grown on CEF with the presence of growth media of 1X 199 medium (Sigma) at 37°C in 5% CO₂ (Figure 2).

Figure 1. PCR products from fpIBD1 showing the VP2-specific band (~1.6 kb). Lanes (a) Primers VP2 F (+BamHI site) and VP2 R (+BamHI site). Lane (b) Primers VP2 F (+EcoRI site) and VP2 R (+NotI site). M - DNA marker.

Figure 2. Blue plaques of fpIBD1 on X-gal overlay Agar (two different dilutions).

The vIBDV strain F52/70 [17] was used, and its titre was kindly determined by Dr Adriaan van Loon (Intervet BV, The Netherlands) [18]. Based on earlier studies, the dose of virus selected was 102.3 EID50 vIBDV strain F52/70, which can overcome the protection provided by fpIBD1 and cause damage to the bursa of Fabricius, that can be measured as bursal lesion score in 2-3 week-old RIR chicks (Davison TF, personal communication).

2.3. Generation of novel fpIBD1 recombinants

fpIBD1 mutants with knockout of IL-18bp genes were selected using trans-dominant selection [19] for the *Escherichia coli* guanine phosphoribosyltransferase (gpt) gene and checked by PCR [16]. Deleted recombination constructs, containing 50 bp from either end of Fowlpox virus ORFs 073 and 214 as well as 500 bp flanking sequences, were inserted into the BamHI and HindIII restriction sites of vector pGNR [16]. The constructs were then transfected, using Lipofectin (Invitrogen), into CEF infected with fpIBD1. Following 37°C in 5% CO₂ overnight incubation, the culture medium was discarded and replaced with 1X 199 medium + 2% new born bovine serum (NBBS) containing mycophenolic acid, xanthine and hypoxanthine (MXH) solution and reincubated for 2-4 days until a cytopathic effect was apparent. The virus was released by freeze/thawing the culture three times then plaqued out under MXH selection.

Gpt⁺ recombinant clones were plaque-purified three times in MXH selective medium then further purified without selection until they became gpt⁻ (as determined by failure to plaque under MXH selective medium), that was confirmed by PCR.

For production of recombinants expressing chIL-18, a recombination vector was constructed. Briefly, pGEM-T::chIL-18 was digested with NotI, chIL-18 was then inserted into pEFgpt12S (containing S promoter). Sp+chIL-18 was then inserted into the PC-1 plasmid (pFPV-PC-1) to result in pFPV-PC-1::Sp+chIL-18, which was the target clone in which the chIL-18 gene, under the control of a synthetic early-late promoter, was inserted into the non-essential PC-1 gene (ORF FPV030) in a plasmid carrying the gpt gene under the control of the Vaccinia virus p7.5 promoter. CEF infected with parental fpIBD1, fpIBD1Δ073 and fpIBD1Δ214 viruses were then transfected with the pFPV-PC-1::S-promoter/chIL-18 plasmid. Gpt⁺ recombinants were selected and plaque purified three times. Insertion of the expression and selection cassette into the PC-1 gene was confirmed by PCR. The six different recombinant viruses were titrated. Viruses carrying the gpt reporter gene (i.e., those that contain chIL-18) always had lower titres (Table 1).

Table 1. Titration of the six vaccines.

Virus	Final concentration (pfu/ml)
fpIBD1	1X10 ⁹
fpIBD1Δ073	2X10 ⁹
fpIBD1Δ214	1X10 ⁹
fpIBD1::IL-18	2X10 ⁸
fpIBD1Δ073::IL-18	2X10 ⁸
fpIBD1Δ214::IL-18	3X10 ⁸

2.4. Experimental design

Seventy day-of-hatch chicks were divided into 14 groups, 7 groups of 7 birds per group were challenged with IBDV, with 7 groups of 3 birds per group as a control, in 4 separate rooms (Table 2). Chicks (groups 1 and 2) were used as unvaccinated control groups; the first group as a negative control without challenge and the second group was positive control as it was challenged with the IBDV. Chicks (groups 3-14) received the first vaccination of 50 µl volume at one week of age with 10⁷ pfu fpIBD1 and altered fpIBD1. The vaccination site was, as per fowlpox vaccination, in the wing-web with puncturing the site of vaccination many times using a hypodermic needle and a booster vaccination with same doses was carried out two weeks later. Ten days following the booster vaccination, chickens in groups from 2 to 8 were challenged with IBDV. The challenge dose of 10^{2.3} EID₅₀ of IBDV strain F52/70 in a volume of 100 µl was given by intranasal route. Birds from the challenged unvaccinated group (group 2) were bled daily after the day of challenge. Blood (50 µl) was taken into 350 µl RTL buffer, after puncturing the wing vein with a needle. Five days after challenge, all birds were killed and the bursae removed and cut into 3 pieces. A small piece was taken into RNA Later for RNA extraction and 2 larger pieces were taken, one for immunohistochemistry and the other one into formalin solution for H&E staining to determine bursal damage.

Table 2. Challenge experiment.

Room	Group	Treatment	No. of birds
1	1	Unvaccinated and unchallenged (negative control)	3
2	2	Unvaccinated and challenged (positive control)	7
3	3	Vaccinated with fpIBD1 and challenged	7
	4	Vaccinated with fpIBD1Δ073 and challenged	7
	5	Vaccinated with fpIBD1Δ214 and challenged	7
	6	Vaccinated with fpIBD1::IL18 and challenged	7
	7	Vaccinated with fpIBD1Δ073::IL18 and challenged	7
	8	Vaccinated with fpIBD1Δ214::IL-18 and challenged	7
	9	Vaccinated with fpIBD1	3
4	10	Vaccinated with fpIBD1Δ073	3
	11	Vaccinated with fpIBD1Δ214	3
	12	Vaccinated with fpIBD1::IL18	3
	13	Vaccinated with fpIBD1Δ073::IL18	3
	14	Vaccinated with fpIBD1Δ214::IL-18	3

2.5. Sample processing

2.5.1. RNA extraction

Bursal tissue (~30 mg) was homogenised using a Bead mill (Retsch MM300). Briefly, the bursal tissue was placed in a 2 ml Safe-lock Eppendorf tube with 600 µl lysis buffer RLT. A 5mm stainless steel bead was added per tube. The tubes were placed in adaptors for the bead mill and run for 4 min at 20 Hz. RNA was extracted from tissues and blood using the RNeasy mini kit (Qiagen) as per manufacturer’s instructions and stored at -70°C.

2.5.2. Frozen sections for immunohistochemical staining

Each bursal tissue sample was put on a 2.5 cm² cork tile. The bursal tissue sample was then covered with Tissue-Tek® OCT™ Compound and snap-frozen in a dry-ice/iso-pentane bath and then transferred immediately to a tank of liquid nitrogen. Frozen blocks were then stored at -70°C and sections were prepared for immunohistochemical staining.

Bursal tissue sections of 6-8 µm for each section was cut using a cryostat. Each section was picked up and placed on a glass slide and fixed in acetone for 10 min and left to air-dry. Staining of bursal tissue sections was done using a Vectastain® ABC α-mouse IgG HPR staining kit (Vector

Laboratories, Burlingame, CA, USA) as per the manufacture’s protocol. Image-Pro® Plus soft-ware version 4.0 was used to count the number of positively stained cells as a percentage of the field of view at a magnification power of 100X. The monoclonal antibodies used were R63 [3] for IBDV and AV20 [20] for B cells.

2.5.3. H&E staining

Each bursal section from every bird was put into 40 ml formalin and stained with haematoxylin and eosin (H&E) to look for bursal damage.

2.6. Real-time quantitative RT-PCR

Quantitative real-time RT-PCR was carried out for IBDV and 28S [21]. A probe against 28S rRNA was used to control for variations in quantities of total RNA between samples. IBDV-specific forward and reverse primers were identified and designed from the genomic IBDV segment A [22]. Primers and probes (Table 3) were designed using the Prime Express software program (PE Applied Biosystems). All probes were labelled with the fluorescent reporter dye 5-carboxyfluorescein (FAM) at the 5’ end and the quencher dye N,N,N,N’-tetramethyl-6-carboxyrhodamine (TAMRA) at the 3’ end (PE Applied Biosystems).

Table 3. Primers and probes for real-time quantitative RT-PCR.

RNA target	Primer/Probe*	Sequence (5’-3’)
28S	F	GGC GAA GCC AGA GGA AAC T
	R	GAC GAC CGA TTT GCA CGT C
	Probe	AGG ACC GCT ACG GAC CTC CAC CA
IBDV (VP2)	F	GAG GTG GCC GAC CTC AAC T
	R	AGC CCG GAT TAT GTC TTT GAA G
	Probe	TCC CCT GAA GAT TGC AGG AGC ATT TG

Reagents from the TaqMan® EZ RT-PCR kit (PE Applied Biosystems) were used for the RT-PCR. RNA is first reverse transcribed to cDNA by *rTth* DNA polymerase (not shown) and amplified by PCR. Separation of the reporter dye from the quencher dye leads to increase of the fluorescence during each extension cycle of the PCR. Amplification and detection of specific products was performed using the ABI PRISM™ 7700 Sequence Detection System, with cycle profile as follows: 1 cycle of 50°C for 2 min, 96°C for 5 min, 60°C for 30 min and 95°C for 5 min, and 40 cycles of 94°C for 20 sec and 59°C for 1 min. Results are expressed in terms of the cycle threshold (C_t), a statistically significant increase in fluorescence.

2.7. Construction of standard curves for quantitative PCR and RT-PCR assays

In every experiment, 28S rRNA standard curves were generated and included. For the generation of standard curves, a regression analysis of the mean values for the log₁₀ diluted RNA was used. The slope of the regression line for each of the target RNAs gives a measure of the efficiency of the reaction for that particular prime/probe combination. To control for the variation in input test RNA, due to variations between samples and in RNA preparation, the C_t values for each sample were standardised using the C_t value of the 28S rRNA product for the same sample. All 28S rRNA C_t values were similar for samples within and between experiments. The efficiency of the 28S rRNA reaction, that are seen in slope of the log₁₀ dilution series regression line, was used to calculate differences in input total RNA.

3. Results

3.1. Protection from IBDV challenge by the recombinant vaccine *fpIBD1* and the new viral constructs

Within 2 days, birds vaccinated with parental fpIBD1 or manipulated fpIBD1 developed pocks, at the site of inoculation, which disappeared by 10 days. Protection from IBDV challenge by fpIBD1 recombinant vaccine and the altered fpIBD1 was measured by the appearance of IBD clinical signs, bursal damage scoring index of Muskett et al. [23] (Table 4 & Figure 3), and viral loads (IBDV) in the bursa, using immunohistochemical staining and real-time quantitative RT-PCR, at 5 days post-infection (dpi).

Figure 3. Sections of bursae stained with H&E from birds infected with vIBDV strain F52/70, showing different bursal damage scores as detailed in Table 3. A = bursal damage score of 0, B = bursal damage score of 1, C = bursal damage score of 2, D = bursal damage score of 3, E = bursal damage score of 4, F = bursal damage score of 5. Arrows indicate the cortex (1), medulla (2) and cortico-medullary junction (3) of a bursal follicle.

Table 4. Bursal damage scores for different groups after infection with vIBDV based on the histological scoring system* of Muskett et al. [23].

Vaccination	IBDV challenge	Bursal Damage Score					
		0	1	2	3	4	5
-	-	5	-	-	-	-	-
-	+	-	-	-	1	3	1
fpIBD1	+	1	3	1	-	-	-
fpIBD1Δ073	+	2	2	1	-	-	-
fpIBD1Δ214	+	4	1	-	-	-	-
fpIBD1::IL-18	+	5	-	-	-	-	-
fpIBD1Δ073::IL-18	+	5	-	-	-	-	-
fpIBD1Δ214::IL-18	+	5	-	-	-	-	-

Severe bursal damage was observed for all infected, unvaccinated birds (Table 4). Four out of five (80%) fpIBD1-vaccinated birds were not protected. Three birds out of five (60%) vaccinated with

fpIBD1Δ073 were not protected. Only one bird out of five (20%) vaccinated with fpIBD1Δ214 was not protected. Interestingly, no bursal damage was seen for all birds vaccinated with viral constructs containing IL-18.

In unvaccinated challenged birds, as IBDV targeted B cells in bursae of infected, huge depletion of B cells was obvious. Some B cell depletion was seen in the bursae of birds vaccinated with fpIBD1. Very little B cell depletion was seen in the bursae of birds that were vaccinated with the knockout viruses 073 and 214 and no B cell depletion was observed in the bursae of birds that were vaccinated with the viruses that contained chIL-18 (Figure 4).

Figure 4. Bursal tissue sections from different groups taken at 5 dpi. with the vIBDV strain F52/70. The sections were stained with the anti-B cell monoclonal antibody, AV20, and counterstained with haematoxylin. A = unvaccinated and unchallenged (-ve control), B = vaccinated with fpIBD1 and challenged, C = vaccinated with fpIBD1Δ214::IL-18 and challenged, D = unvaccinated and challenged (+ve control).

3.2. Detection of IBDV using immunohistochemistry

Bursa tissues of unvaccinated and challenged chickens were swamped with the virus. Clear destruction of the bursa of Fabricius can be seen. On the other hand, no IBDV has been detected in the bursa samples of vaccinated chickens (Figure 5).

Figure 5. Bursal tissue sections stained with the anti-IBDV monoclonal antibody, R63, and counterstained with H at 5 dpi. A = Unvaccinated and unchallenged, B = vaccinated with fpIBD1 and challenged, C = unvaccinated and challenged. Challenge was with $10^{2.3}$ EID₅₀ vIBDV strain F52/70.

3.3. Detection of IBDV using real-time quantitative RT-PCR

Viral RNA in 50 μ l of whole blood extracted from infected chickens (unvaccinated) over the first 5 dpi with vIBDV strain F52/70 (every 24 h) was quantified. The total number of birds in this group was 7 birds. 5 birds came to the clinical end-point by 3 dpi and 2 birds survived until the end of the experiment (5 dpi). The results show that IBDV levels in the blood reach a peak at 3 dpi. The two surviving birds had lower levels of IBDV in the blood compared to the other birds (Figure 6).

Figure 6. IBDV mRNA levels in the blood of an unvaccinated birds (-ve control) and birds challenged with IBDV $10^{2.3}$ EID₅₀ strain F52/70 were quantified by real-time quantitative RT-PCR. Birds nos 4 and 6 survived until the end of the experiment, whereas the other birds reached the clinical end-point by 3 dpi. Results are expressed as 40-Ct values.

IBDV was detected in the bursa at very high levels in infected, unvaccinated birds (Fig 7). There was a low level of IBDV in the bursae of birds vaccinated with fpIBD1 or with fpIBD1Δ073 and lower levels still in the bursae of birds vaccinated with fpIBD1Δ214. Interestingly, hardly any IBDV was detected in the bursae of birds vaccinated with fpIBD1::IL-18, and even more interestingly, no virus was detected in the bursae of birds vaccinated with either fpIBD1Δ073::IL-18 or fpIBD1Δ214::IL-18 (Figure 7). The experiment was repeated and similar results were obtained.

Figure 7. Viral loads (vIBDV strain F52/70) in the bursa 5 d.p.i. (1): -ve control; (2): +ve control (vIBDV); (3): fpIBD1; (4): fpIBD1Δ073; (5): fpIBD1Δ214; (6): fpIBD1::IL18; (7): fpIBD1Δ073::IL18; (8): fpIBD1Δ214::IL18; (9): fpIBD1; (10): fpIBD1Δ073; (11): fpIBD1Δ214; (12): fpIBD1::IL18; (13): fpIBD1Δ073::IL18; (14): fpIBD1Δ214::IL18; (Groups 2-8): Challenged with vIBDV; (Groups 9-14 and group 1): No challenge.

4. Discussion

In chickens, it has been shown that the Th1/Th2 paradigm is occurring similar to mammals [24]. In order to have therapeutics efforts for a specific disease, it is important to first understand the protection that can be provided by the immune response and then to apply the response to establish a strategy for vaccination. For example, to have a good immune response against viruses as an example of intracellular pathogens, priming immunization should be directed towards Th1 responses. This can be achieved by studying the cytokines that are produced during infection as well as what type of immune cell populations that have been affected. Many cytokine profiles can now be easily measured during the course of an any studied infection. This was the case for cytokine response and production in the bursa of Fabricius during IBDV infection [25].

Pro-inflammatory cytokine response in the bursa of Fabricius were detected during IBDV infection, by increasing of the pro-inflammatory cytokines IL-1β, IL-6 and IL-8, and of TGF-β4, the anti-inflammatory cytokine, down-regulation. IFN-γ expression was increased in infected bursae, presumably reflecting this inflammatory response, that have been reported in earlier published results [26,27] suggesting cell-mediated immune responses are activated in order to overcome the infection. Chicken IFN-γ also has anti-viral activity [28] and the increased levels of IFN-γ mRNA are consistent with enhanced production of IFN-γ proteins that should have anti-viral activity.

Pathogens continually evolve in order to evade the host’s immune responses and there is growing evidence that, in response to the intensive use of vaccines, some viruses have increased in virulence, overcoming vaccine-induced protection [29,30].

The requirements for an effective poultry vaccine include safety and stimulation of appropriate and long-lasting immune responses that protect against the pathogen and produce minimal side-effects. New technologies such as recombinant viral vectors vaccines may offer a solution and, indeed, experimental vaccines like these have provided encouraging results after challenge with IBDV [10]. New vaccine strategies have emerged in recent years which take advantage of recombinant DNA technology and improved immunological knowledge, for example, recombinant subunit vaccines that contain only the immunogenic part of a pathogen that could have many advantages over live attenuated or inactivated vaccines.

For expression in fowlpox, the gene of interest, VP2 of IBDV in the fpIBD1, is placed next to a poxvirus promoter and inserted into the virus genome by homologous recombination or direct

ligation. Using poxvirus promoters is necessary as the poxvirus transcriptional apparatus does not recognize cellular and other viral promoters.

fpIBD1 is a recombinant FPV, which expresses VP2 from viral strain F52/70 IBDV under a vaccinia promoter within the recombinant fowlpox vaccine [10]. The whole of VP2 and part of VP4 was inserted in the same ORF as a β -galactosidase gene. This results in the production of a fusion protein, which allows the identification of recombinant viruses. When administered at 1 and 14 days of age, fpIBD1 protected against mortality resulting from challenge of 4-week-old RIR chickens with virulent and very virulent strains of IBDV, F52/70 and CS89 respectively [20].

No bursal damage in the Bursa of Fabricius was seen in RIR chickens that have been vaccinated with fpIBD1, and then challenged with IBDV strain F52/70 at doses of $10^{1.3}$ EID₅₀ or $10^{1.7}$ EID₅₀. The dose of challenge virus that breaks the protection stimulated by fpIBD1 was determined and the virus challenge dose chosen for the challenge animal experiments was $10^{2.3}$ EID₅₀ [31]. These results were obtained using outbred RIR chickens and are consistent with Shaw and Davison's observations [13], that protection mediated by fpIBD1 can be broken by increasing the dose of challenge virus. As at low challenge titres, fpIBD1 protected against bursal depletion as well as mortality but at higher titres, bursal lesions were evident.

Interestingly, no antibody against IBDV was detectable after vaccination with fpIBD1 and prior to challenge with IBDV [10,13], which would suggest that only a cellular immune response is involved in the protective response and the control of IBDV, and that antibodies are not essential for providing protection. Also, IBDV does not infect T lymphocytes [32,33].

There are many possible views to explain why fpIBD1 does not provide complete protection. In IBDV genome, VP2 is not expressed separately, but as part of a polyprotein that is cleaved by VP4 [34,35]. One possibility could be that only low levels of the fusion protein are produced by this recombinant. This could be due to the presence of vaccinia promoter, or could be that fpIBD1 may not express correctly-folded VP2, due to the absence of VP4, or another possibility that the expression of VP2 was at very low levels so does not stimulate an antibody response. A second possibility is that the fpIBD1 is not replicating very well in the chickens. However, antibodies against FPV were produced and detected [10,13], suggesting replication of fpIBD1 occurred. Finally, another possibility that VP2 antigen was not present in the correct conformation.

The Fowlpox virus genome contains many immunomodulatory genes, including an IL-18bp [12,15]. It seemed logical to delete this gene from vectors containing chIL-18 as an adjuvant. However, Fowlpox virus presumably uses its vIL-18bp as part of a strategy to avoid the host immune response. Deleting the vIL-18bp gene might, therefore, have had an adverse effect on the persistence of the fpIBD1 vaccine in the host and could, therefore, have altered the magnitude of the immune response to the vaccine.

A recent study by Gibson et al., is supporting our conclusion that ORF214 in FPV is most likely to be IL-18bp. Their results demonstrated that ORF214 would be likely to inhibit IL-18 activity in the chicken by acting as IL-18bp, whereas the ORF073 would not [36].

Our results showed that a complete protection against IBDV can be provided after insertion of chIL-18 into the recombinant fpIBD1, especially after knocking out the IL-18bp from the vector.

FPV presumably uses its vIL-18BP as part of a strategy to avoid the host immune response. ORF214 is the better candidate for the IL-18BP, as fpIBD1 Δ 214 gave better protection than fpIBD1 or fpIBD1 Δ 073. Despite the use of a challenge dose of IBDV, high enough to overcome protection and cause bursal damage in birds vaccinated with fpIBD1, there was no bursal damage in birds vaccinated with viruses containing chIL-18. Furthermore, no IBDV was detected in the bursae of birds vaccinated with fpIBD1 Δ 214::IL-18.

5. Conclusions

In conclusion, we believe our data indicate that chIL-18 can act as a vaccine adjuvant with fpIBD1 when challenging with a virulent strain of IBDV. In addition, based on the results in this study we may conclude that ORF214 is better candidate to be as IL-18bp.

Author Contributions: Conceptualization, I.E. and P.K.; methodology, I.E.; validation, I.E., L.R., M.S. and P.K.; investigation, I.E.; data curation, I.E., L.R.; writing—original draft preparation, I.E.; writing—review and editing, I.E., L.R., M.S. and P.K.; supervision, P.K. All authors have read and agreed to the published version of the manuscript.

Funding: This research was funded by the Libyan Government through the Libyan Embassy in London as a support for Ibrahim Eldaghayes's PhD.

Institutional Review Board Statement: The study was conducted in accordance with Animals (Scientific Procedures) Act 1986. The animal study was reviewed and approved by the ethics committee of the Institute for Animal Health and the United Kingdom Government Home Office.

Data Availability Statement: All data supporting the findings of this study are available within the manuscript. Any additional data are available from the corresponding author upon reasonable request.

Acknowledgments: The authors would like to thank Stephen Laidlaw, Fred Davison, Colin Butter, the people in the EAH especially Don Hoopre, the Media people especially Richard Oaks and the Histology lab people for their help.

Conflicts of Interest: The authors declare no conflict of interest.
