**Abstract:** In hepatocellular carcinoma (HCC), recurrence usually occurs after curative surgical resection. Currently, no adjuvant therapy has shown to reduce recurrence rates. In our study, the effect of sequential treatment with recombinant mouse-IFN- $\alpha$  (rmIFN- $\alpha$ ) and anti-mouse-PD1 in hepatitis B virus (HBV) clearance was evaluated in mouse model. A phase I trial was conducted to assess the safety, tolerability, and inhibitory effect of sequential therapy with ropeginterferon alfa-2b and nivolumab in HCC recurrence in patients undergone curative surgery for HBV-related HCC. HBV suppression was significantly greater with rmIFN- $\alpha$  and anti-PD1 sequential treatment than with mono-administration in a mouse model. In the Phase I trial, eleven patients completed the sequential therapy with ropeginterferon alfa-2b every two weeks at 450  $\mu$ g for six doses, followed by three doses of nivolumab every two weeks up to 0.75 mg/kg. A notable decrease or clearance of HBV surface antigen was observed in two patients. Dose-limiting toxicity of grade 3 aspartate aminotransferase and alanine transaminase increases was observed in one patient. The maximum tolerated dose was determined. No HCC recurrence was observed. The treatment modality was well tolerated by the patients. These data support further clinical development of sequential therapy as a post-surgery prophylactic measure against HCC recurrence.

**Keywords:** Hepatocellular carcinoma; anti-PD1; ropeginterferon alfa-2b; animal HBV model; clinical trial

## 1. Introduction

Hepatocellular carcinoma (HCC) is a common and deadly cancer worldwide [1]. It is associated with underlying chronic liver pathological conditions, including chronic hepatitis viral infection. Chronic hepatitis B (CHB) contributes to more than 50% of global HCC occurrences [2]. Surgery is usually the curative treatment modality for early-stage HCC. However, cancer recurrence is frequently observed. Tumor recurrence rates are approximately 50% and 70% within 5 and 7 years after surgery [3,4]. Currently, there are no approved therapies to inhibit recurrence. Effective and well-tolerated adjuvant therapies are urgently needed to reduce recurrence.

Programmed cell death 1 (PD-1) is a negative costimulatory receptor expressed primarily on the surface of activated T cells. The binding of PD-1 to its ligand, programmed cell death-1 ligand-1/2 (PD-L1/2), inhibits cytotoxic T cell-mediated immunological responses and elicits an immune checkpoint [5]. Tumor cells upregulate PD-L1 and utilize the PD-1 pathway to escape

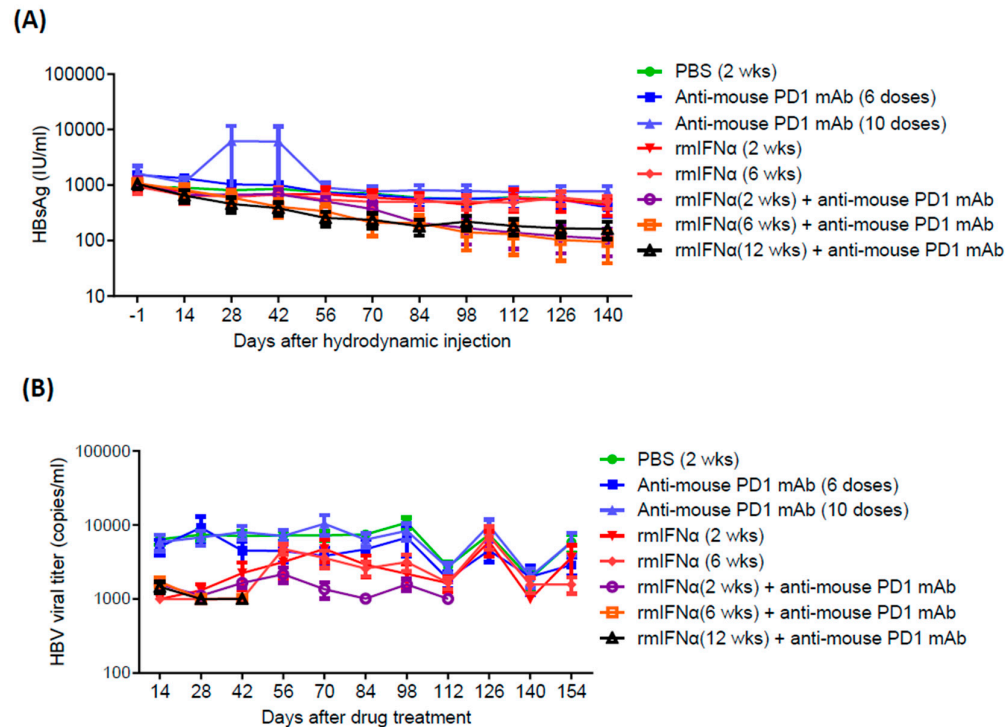

T-cell-mediated immune responses. Anti-PD1 and anti-PD-L1/2 therapeutic antibodies can interfere with the interactions between PD-1 and its ligands, resulting in enhanced anti-tumor immunological response by cytotoxic T cells [5,6]. Anti-PD1 therapy causes a decline or seroclearance of hepatitis B surface antigen (HBsAg) in patients with CHB [7]. HBsAg seroclearance is associated with a lower risk of hepatitis B (HBV)-related HCC [8]. Anti-PD1 therapies have been approved to treat advanced HCC, melanoma, metastatic non-small cell lung cancer, and other advanced malignancies [9]. However, anti-PD-1 therapies are also associated with known toxicities, which may not be suitable in post-surgical adjuvant settings for patients with HCC. A combination therapy that can potentially minimize toxicity and produce a significant anti-cancer effect may be applicable in this setting.

Ropeginterferon alfa-2b represents a new generation PEGylated interferon (IFN)-based therapy with a favorable pharmacokinetic profile. It can be injected less frequently, with fewer flu-like symptoms, injection site reactions, and psychiatric disorders [10–12]. It has been approved for the treatment of polycythemia vera (PV), a myeloproliferative neoplasm (MPN), in the United States and Europe and is currently under development for other indications [13–21]. It appeared to be well-tolerated and showed anti-HBV activities when administered once every two weeks at 450 µg in a Phase II clinical study [22]. Here, we report our findings in an HBV mouse model sequentially treated with a recombinant mouse-IFN-alpha (rmIFN- $\alpha$ ) and an anti-mouse-PD1 antibody and clinical Phase I results of sequential therapy with ropeginterferon alfa-2b and anti-human PD-1 antibody nivolumab in patients with hepatitis B-related HCC after curative surgery.

## 2. Results

### 2.1. Animal modeling data

In our HBV-HDI mouse model, the sequential combination treatment with rmIFN- $\alpha$  and anti-PD1 continuously caused a decline in the mean HBsAg values compared to the phosphate-buffered saline (PBS) control. After treatment with the combination of rmIFN- $\alpha$  and anti-PD1, the mean HBsAg level was one log lower than that in the PBS control group (Figure 1A). In contrast, monotherapy groups treated with either anti-mouse PD1 or rmIFN- $\alpha$  alone showed no significant decline in the HBsAg level when compared to the PBS control (Figure 1A). Compared with the rmIFN- $\alpha$  and anti-mouse PD1 mono-treatment groups, the combination of rmIFN- $\alpha$  and anti-mouse PD1 significantly reduced the HBsAg and HBV viral titer in HBV-carried CBA/CaJ mice (Figure 1A to B). In addition, the HBsAg clearance rate was 44.4% (4/9) in those mice receiving 6-week treatment of rmIFN- $\alpha$  and anti-mouse PD1, which was higher than that in the monotherapy groups (Table 1). These animal data showed a synergistic effect between rmIFN- $\alpha$  and anti-PD1 for HBV suppression or even clearance in this HBV mouse model. We did not observe any adverse effect on animal body weight, liver function and blood cell production (data not shown).

**Figure 1.** HBsAg (A) and HBV viral titer (B) in HBV-carried CBA/CaJ mice.

**Table 1.** Mean HBsAg and HBsAg clearance rate at the end of animal study.

Treatment Groups	Mean HBsAg (IU/ml)	HBsAg clearance rate
PBS	471.9	0% (0/6)
Anti-PD1 (6 doses)	398.6	20% (2/10)
Anti-PD1 (10 doses)	769.1	10% (1/10)
rmIFN- $\alpha$ (2wk)	441.2	0% (0/6)
rmIFN- $\alpha$ (6wk)	504.7	0% (0/6)
rmIFN- $\alpha$ (2wk) + anti-PD1 (6 doses)	107.8 (p value = 0.0012)	20% (2/10)
rmIFN- $\alpha$ (6wk) + anti-PD1 (6 doses)	94.3 (p value = 0.0009)	44.4% (4/9)
rmIFN- $\alpha$ (12wk) + anti-PD1 (6 doses)	162.1 (p value = 0.0040)	0% (0/10)

## 2.2. Phase I Clinical Study

A phase I study was completed to determine the maximum-tolerated dose (MTD). A total of 12 eligible patients were enrolled (Figure 2), including six patients in Cohort 1 and six in Cohort 2. All patients completed the study treatment except one who withdrew early because of grade 3 anorexia after receiving one dose of ropeginterferon alfa-2b in Cohort 2.

The mean (standard deviation) age of the eligible patients was 61.8 (10.3) years old (Table 2). Six (50%) patients had liver cirrhosis before participating in this study. All patients experienced at least one adverse event (AE) after treatment. Most AEs were either mild or moderate (Table 3). No Grade 4 or 5 events were observed. No severe AEs (SAEs) were observed. Four patients (33.3 %) experienced grade 3 AEs. The most frequent AE was pyrexia (50%), followed by alanine transaminase (ALT) increase (41.7%), aspartate aminotransferase (AST) increase (41.7%), fatigue (33.3%), and neutrophil count decrease (25%).

Dose-limiting toxicities (DLTs) were observed in only one patient. Drug-related grade 3 ALT and AST levels increased in one patient in Cohort 1 who completed ropeginterferon alfa-

2b treatment and received one dose of nivolumab. No DLTs were observed in Cohort 2. However, given that the DLT of Grade 3 ALT and AST increases was observed in Cohort 1 and that there were increased levels of Grade 2 ALT and AST increase in Cohort 2, we defined the dose of ropeginterferon alfa-2b at 450 ug for six doses and nivolumab at 0.75 mg/kg for three doses in Cohort 2 as the MTD for the adjuvant sequential treatment based on the overall safety assessment.

All patients are alive without cancer recurrence as of the date. The mean follow-up period was 716.75 days (minimum: 114 days; maximum: 1416). HBsAg was undetectable in one patient in Cohort 1 at follow-up week 12 and after (Figure 3A). The mean HBsAg levels decreased over time in Cohort 2 during the treatment period (Figure 3B).

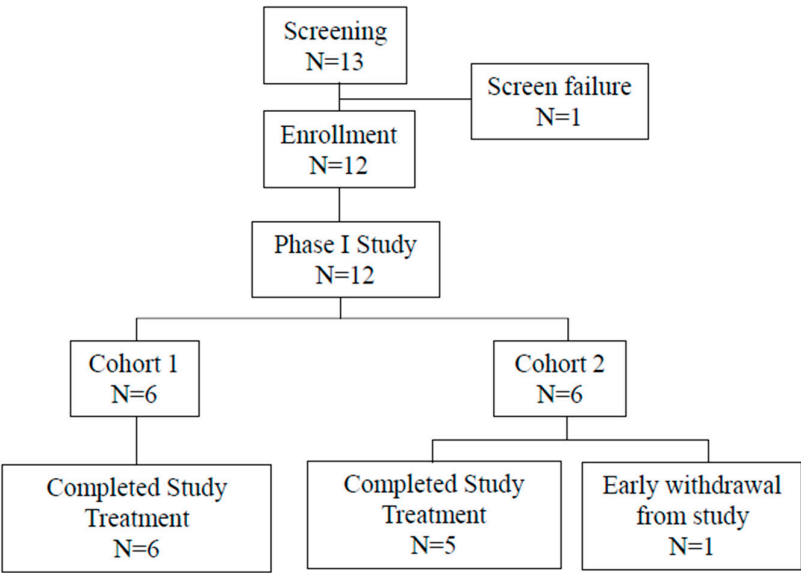

Figure 2. Summary of subject disposition in phase I study.

Table 2. Summary of Demographics and Baseline Characteristics in the Phase I Study.

Characteristics	P1101 + Anti-PD1		
	N=12		
	Cohort 1	Cohort 2	Total

### 3. Discussion

HCC is a common cause of cancer-related deaths, and most HCC cases are associated with HBV infection. Patients with HCC have a high risk of tumor recurrence after surgical resection. Currently, no approved therapies for recurrence inhibition exist. In this report, we showed our animal modeling data that sequential treatment with rmIFN- $\alpha$  and anti-PD1 led to a synergistic effect in HBV suppression and clearance. Our Phase I clinical study further suggested that sequential therapy with ropeginterferon alfa-2b and nivolumab was well-tolerated and might help clear residual HBV infection and inhibit cancer recurrence in post-surgery HBV-infected HCC patients.

PD-L1 is often overexpressed during CHB infection [23]. In HCC patients with CHB, treatment with nivolumab decreased HBsAg levels [7,24]. Nivolumab is approved for HCC treatment in combination with ipilimumab [25]. It is reasonable to assume that anti-PD-1 antibodies may suppress cancer recurrence in HBV-infected patients with HCC who have undergone surgical resection. However, the toxicities associated with anti-PD-1 treatment at approved dose levels and HBV reactivation due to the residual viral genome pose hurdles for its use alone as a prophylactic measure against HCC occurrence [26–28].

Type 1 IFNs, including IFN- $\alpha$  and beta (IFN- $\beta$ ), share the same receptor components. They can slow S phase progression by activating an intra-S phase checkpoint, induce senescence entry, and cause loss of tumorigenicity in solid tumor cells [29]. In addition, they stimulate the immune system to elicit anti-tumor activities, including inducing natural killer cell-dependent anti-tumor responses [30], and activating CD8<sup>+</sup> T cell-mediated anti-tumor responses [31]. The combined anti-tumor activities can inhibit tumor formation. Pegylated IFN- $\alpha$  has been shown to have anti-HBV activities and is approved for the treatment patients with HBV infection [32]. Therefore, an effective PEGylated IFN- $\alpha$  treatment that can exert both anti-cancer and anti-HBV activities may reduce the need of the anti-PD1 treatment at a high dose level. Their sequential combination treatment may potentially lead to the eradication of residual tumor cells or newly derived tumor cells from HBV infection in patients with HBV-positive HCC after surgery. Our results suggest that sequential therapy with ropeginterferon alfa-2b and nivolumab may be a promising regimen for inhibiting cancer recurrence after surgery in HBV-infected HCC patients.

### 4. Methods

#### 4.1. HDI mouse model:

Six- to eight-week-old male CBA/Caj mice were bred at the National Taiwan University Laboratory Animal Center. The mice were intravenously injected with 10  $\mu$ g of HBV genotype A DNA plasmid dissolved in PBS equivalent to approximately 8% of the mouse's body weight. Serum HBsAg and HBV DNA were measured to monitor the HBV persistence. All experiments were performed according to the guidelines established by the Institutional Animal Care and Use Committee at the National Taiwan University College of Medicine.

#### 4.2. Preclinical Materials:

Anti-mouse PD1 (clone RMP-17) is a monoclonal antibody targeting mouse PD-1 generated by hybridoma screening at the PharmaEssentia Corporation Research Laboratory. rmIFN- $\alpha$  was produced using the *Escherichia coli* expression system at PharmaEssentia Corporation.

#### 4.3. Treatment of HBV-carried CBA/Caj mice:

Mice were separated into eight groups to investigate the effect of rmIFN- $\alpha$  in combination with the anti-mouse PD1. The drug dosages and routes of drug administration are described below:

Group 1 (control): Six HBV-carried CBA/Caj mice were subcutaneously (s.c.) injected with 200  $\mu$ l PBS (every other day [Q2D]  $\times$  8, days 0~14).

Group 2: Six HBV-carried CBA/CaJ mice were s.c. injected with 800 IU/g of rmIFN- $\alpha$  (Q2D x 8, day 0~14).

Group 3: Six HBV-carried CBA/CaJ mice were s.c. injected with 800 IU/g of rmIFN- $\alpha$  (Q2D x 22, day 0~42)

Group 4: Ten HBV-carried CBA/CaJ mice were intraperitoneally (i.p.) injected with 32  $\mu$ g/g of the anti-mouse PD1 antibody (Ab) (Q2D x 6, days 16~26).

Group 5: Ten HBV-carried CBA/CaJ mice were i.p. injected with 32  $\mu$ g/g of anti-mouse PD1 Ab (Q2D x 10, days 16~34).

Group 6: Ten HBV-carried CBA/CaJ mice were s.c. injected with 800 IU/g of rmIFN- $\alpha$  (Q2D x 8, days 0~14), and then, i.p. injected with 32  $\mu$ g/g of the anti-PD1 Ab (Q2D x 6, days 16~26).

Group 7: Ten HBV-carried CBA/CaJ mice were s.c. injected with 800 IU/g of rmIFN- $\alpha$  (Q2D x 22, days 0~42), and then, i.p. injected with 32  $\mu$ g/g of the anti-PD1 Ab (Q2D x 6, days 44~54).

Group 8: Ten HBV-carried CBA/CaJ mice were s.c. injected with 800 IU/g of rmIFN- $\alpha$  (Q2D x 43, days 0~84), and then, i.p. injected with 32  $\mu$ g/g of the anti-PD1 Ab (Q2D x 6, days 86~96).

#### 4.4. Clinical materials:

Ropeginterferon alfa-2b was produced by PharmaEssentia Corporation. It was provided as a prefilled syringe of 500  $\mu$ g/1.0 mL. Nivolumab (OPDIVO®, Bristol-Myers Squibb Company) was obtained via investigator prescription in the dosage form of 20 mg/2 mL or 100 mg/10 mL per vial.

#### 4.5. Study Design:

This clinical study was designed as a Phase I/II trial. The Phase I study aimed to evaluate the safety and tolerability and define the MTD of the sequential administration of ropeginterferon alfa-2b and nivolumab in patients who had received curative surgery of hepatitis B-related HCC. The Phase II trial was designed to further evaluate the safety and prophylactic effect of sequential administration of ropeginterferon alfa-2b and nivolumab at the MTD. Phase I was conducted at the National Taiwan University Hospital (NTUH) Taiwan (approval number: 201710061MIPB). The Phase I study was completed, and Phase II has not yet started.

The sequential administration of ropeginterferon alfa-2b and nivolumab was assessed using a 3+3 dose escalation scheme. Eligible patients were enrolled into four dose cohorts to receive the six doses of ropeginterferon alfa-2b at 450  $\mu$ g once every two weeks, followed by three doses of nivolumab at a pre-determined dose level by cohort, i.e., 0.3 mg/kg in Cohort 1; 0.75 mg/kg in Cohort 2; 1.5 mg/kg in Cohort 3, and 3 mg/kg in Cohort 4, every two weeks. Patients were followed up by a site visit for an additional 48 weeks after completion of the study treatment. Disease progression and survival status were planned to be continually monitored. Twelve patients were enrolled in this study.

#### 4.6. Patients:

Patients with HBV-related HCC who received the surgical resection within eight weeks were enrolled. Other major inclusion criteria included positive results for HBsAg, undetectable HBV DNA, compensated liver disease, normal fundoscopic examination, and an Eastern Cooperative Oncology Group Performance Status score of 0 to 1. The major exclusion criteria included HCC that is not related to hepatitis B, vascular invasion of HCC on imaging diagnosis, patients who had undergone transcatheter arterial embolization or chemoembolization, transcatheter arterial infusion, or chemolipiodolization in combination with surgery, and a concurrent active malignancy other than HCC.

### 5. Conclusion

Our animal data demonstrated a synergistic effect between rmIFN- $\alpha$  and anti-PD1 for HBV suppression or even clearance. This effect was observed in patients with HCC treated with sequential treatment of ropeginterferon alfa-2b and nivolumab in a clinical Phase 1 setting. Most AEs were mild

or moderate. Increased liver transaminase increases were common but not associated with increased bilirubin levels or clinical symptoms. No unexpected AEs were observed. The MTD of sequential combination therapy with ropeginterferon alfa-2b and nivolumab was determined. Further exploration and clinical development of this combination therapy are warranted.

**Author Contributions:** Each author contributed to the work and is responsible for its content. P-J. C. and C-R. W. designed and conducted the animal experiment. P-J. C. and M-C. H. enrolled and treated patients. All authors participated in the writing and reviewing of the manuscript and agreed to the publication of this article.

**Funding:** This animal experiment and phase I/II study were partially sponsored by the PharmaEssentia Corporation.

**Institutional Review Board Statement:** Animal experiments were performed following the guidelines established by the Institutional Animal Care and Use Committee of the National Taiwan University College of Medicine. This phase I/II clinical study was approved by the Institutional Review Board of NTUH (201710061MIPB) and followed the principles of the Declaration of Helsinki for all human experimental investigations. Phase I/II clinical studies were registered at ClinicalTrials.gov (NCT04233840, P1101 and Anti-PD1 for After Curative Surgery of Hepatitis B-related Hepatocellular Carcinoma).

**Informed Consent Statement:** Informed consent was obtained from all participating patients.

**Data Availability Statement:** Data will be available to external researchers upon reasonable request from the investigator and PharmaEssentia.

**Acknowledgments:** The authors thank all the other participants, including the study nurse, coordinator, other investigators, and PharmaEssentia team members involved in this study. We are grateful to the patients and their families.

**Conflicts of Interest:** A Qin and C-Y. Tsai work for PharmaEssentia Corporation. P-J Chen served as a consultant for PharmaEssentia Corporation. Other authors declare no conflicts of interest.
