**Abstract:** Genetic engineering has become an essential element in developing climate-resilient crops and environmental sustainable solutions to respond to the increasing need for global food security. Genome editing using CRISPR/Cas [Clustered regulatory interspaced short palindromic repeat (CRISPR)-associated protein (Cas)] technology is being applied to a variety of organisms, including plants. This technique has become popular because of its high specificity, effectiveness, and low production cost. Therefore, this technology has the potential to revolutionize agriculture and contribute to global food security. Over the past few years, increasing efforts have been seen in its application in developing higher-yielding, nutrition rich, disease resistant, stress-tolerant “crops” fruits and vegetables. Cas proteins such as Cas9, Cas12, Cas13, and Cas14, among others, have distinct architectures and have been used to create new genetic tools that improve features that are important for agriculture. The versatility of Cas has accelerated genomic analysis and facilitated the use of CRISPR/Cas to manipulate and alter nucleic acid sequences in cells of different organisms. This review provides the evolution of CRISPR technology exploring its mechanisms and contrasting it with traditional breeding and transgenic approaches to improve different stress tolerance. We have also discussed the CRISPR/Cas system and explored three Cas proteins that are currently known to exist: Cas12, Cas13, and Cas14 and their potential to generate foreign DNA free or non-transgenic crops that could be easily regulated for commercialization in most countries.

**Keywords:** CRISPR-Cas system; crop improvement; genome engineering; prime editing

## 1. Introduction

The world population is about to reach 10 billion in the coming years. This increased rate of population rise would result in increased global need for food followed by production [1]. However, the reduction of agricultural land caused by rapid urbanization and industrialization and reduction in fresh produce due to extreme weather accompanied by environmental stressors like climate change and global warming limit agriculture and food production, which may threaten food security [2]. Breeding practices have been helpful over decades in providing us improved crops. However, one of the barriers to de novo domestication through gene editing is the lack of expertise of botanists in wild-plant biology and in recent times, we are in need of novel and efficient tools that could improve crop traits in a shorter time frame. Various techniques have been developed that allow us to

modify genetic sequences specifically such as, transcription activator-like effector nucleases (TALENs), RNAi (RNAi), zinc finger nucleases (ZFNs) and CRISPR/Cas9 have revolutionized crop engineering by making it easier to create crops with higher yield and other desirable characteristics. Among them, the best state-of-the-art technology is CRISPR/Cas genome editing that is gaining popularity because of its boarder application across different organisms [3]. Different genome editing methods have been well compared and the potential use of CRISPR/Cas9 technology in precision plant breeding has been reviewed in detail by Sun et al., 2016 and Chen et al., 2019 [4,5]. CRISPR–Cas system actually originated from the defense mechanism that bacteria use based on RNA, and they recognize and eliminate foreign DNA from invading plasmids and bacteriophages and are thus considered a type of bacterial “immune system” [6]. Overall, the CRISPR/Cas9 modifies genes through exact cutting of DNA, followed by the natural mechanisms of DNA repair [3,7]. The adoption of genome-edited plants by the general public and regulatory agencies is also impacted by these strategies [8].

In this review, we provide an overview of the most recent developments in CRISPR/Cas technology, the functional processes of all identified Cas proteins, and their use in contemporary horticulture and agriculture.

## 2. History of CRISPR/Cas System

Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) was first identified in *E.coli* in 1987 by a Japanese scientist, Yoshizumi Ishino, and his team, as unique repetitive DNA sequences interspersed with spacer sequences [9]. Later, such sequences have been identified in *Salmonella enterica* and *Shigella dysenteries*, two types of enterobacteria, as well as in other *E. coli* strains. Similar to this, when examining Mycobacterium TB strains, researchers found 36 bp repetitions scattered with unique 35–41 bp spacers. In the ensuing investigations, this CRISPR array was found in the genomes of 40% of archaea and 90% of bacteria. The biological purpose of CRISPR was a mystery for some time due to a lack of required spacer or protospacer genome sequence data. It is only in early 2000s that it was discovered that the bacteria possessing these homologous spacer sequences like bacteriophages and viruses were immune to the attack, suggesting their role in adaptive immunity in prokaryotes. Following this research, it has been found that when a bacterium is challenged by a virus, spacer sequences in CRISPR array are transcribed and guided by Cas protein to cleave the viral DNA or RNA to prevent further infection. In addition to the requirement of Cas protein, the CRISPR system also needs a short 2-6 nucleotide protospacer adjacent motif sequence (PAM) placed adjacent to the sequence identified by Cas protein (Figure 1). This ability of the bacterial adaptive immune system and the ease of selecting the target genomic location based on shorter PAM requirement has resulted in precise genome editing in various organisms for varied applications [10].

**Figure 1.** The CRISPR/Cas adaptive immunity system involves three stages: CRISPR adaptation, CRISPR RNA biogenesis, and CRISPR interference. In the adaption stage, viruses trigger Cas1 and Cas2 modules, cleaving invading sequences. In the biogenesis stage, the CRISPR array is transcribed into mature crRNA molecules, forming effector complexes with Cas proteins.

### 3. Nomenclature and Mechanism of CRISPR/Cas System

The CRISPR-Cas system has been divided into two main categories and several subtypes based on the complexity of the effector proteins, genomic location, pre-crRNA processing and interference. The diversity of CRISPR-Cas has increased over the past years and the evolutionary classification of this system and Cas genes has been well documented by Makarova et al., 2019 [11]. In this review, we have discussed the two main classes of CRISPR-Cas system with focus on Cas proteins that have the potential for use in agriculture.

CRISPR-Cas system is mainly classified in two main classes-I and II. In the Class 1 system, multiple effector proteins are required for the RNA-guided target cleavage, while in Class 2, only one RNA-guided endonuclease is required for the DNA sequence cleavage. Three types of CRISPR are present in the Class 1 system: I, III, and IV, while three types are present in the Class 2 system: II, V, and VI. The Cas3 signature gene, which codes for an immune protein containing a helicase to unravel DNA-DNA and RNA-DNA duplexes, is found in the type I system's CRISPR/Cas locus. The multidomain Cas9 (CRISPR-associated protein 9) that the type II locus generates cleaves and targets dsDNA. The cas10 signature gene is present in type III CRISPR/Cas, along with a multidomain protein with a palm domain that can target ssDNA. Other Cas proteins like csf1 (large subunit, cas8-like) signature protein belongs to type IV locus and the RuvC gene, encoded by the CRISPR from *Prevotella* and *Francisella* 1 (Cpf1), C2c1 or C2c3 protein, which is carried by the type V locus, carries

the Cas12 signature gene (a DNA repair-related *E. coli* protein) domain. This domain cleaves either dsDNA or ssDNA. Type VI has a nucleotide-binding domain (HEPN) called Cas13 (C2c2) that is responsible for cleaving ssRNA in higher eukaryotes and prokaryotes. (Table 1)

**Table 1.** Classification of CRISPR-Cas system: Types of Cas proteins with their target molecule.

CRISPR/Cas system used	Host Organism	Name of the effector	Types of Protein	Target molecule	Reference
Cas7, Cas5, Cas8, and Cas3	<i>E. coli</i>	Cas3, Cascade, and crRNA	Cas 3	ssDNA	[80]
Cas7, Cas5, and Cas1	<i>S. epidermics</i>	Cmr/Csm, crRNA, and Cas10	Cas 6	ssDNA	[81]
Cas7, Cas5, and Csf1	-	-	Csf1	-	[82]
Cas9	<i>S. thermophilus</i> and <i>S. pyogenes</i>	Cas9, tracrRNA, and crRNA	Cas9	dsDNA	[83]
Cas12	<i>F. novicida</i>	Cpf1, crRNA and tracrRNA	Cpf1	ssDNA and dsDNA	[84]
Cas13	-	C2c1, and crRNA	C2c2	ssRNA	[85]

Different groups of bacteria and many Archaea use different CRISPR system to defend themselves against foreign nucleic acids, such as viruses and plasmids. The taxonomic distribution of the major classes of CRISPR-Cas system in different groups of bacteria and Archaea have been well documented to show the distribution of different Cas proteins in these organisms [12]. The CRISPR-Cas system could be explained to act in three stages: adaptation, expression and interference. Briefly, following the infection by the viruses, the bacterial host genome's CRISPR repeat sequences are decoded as arrays, and type II CRISPR systems integrate sequences from overrunning DNA between them. The CRISPR reprise arrays are repeated to form crRNA, each containing a different sequence taken from the DNA it overlaps, called the "protospacer" sequence. This sequence makes up a part of the CRISPR reprise. In type II system, the trans-activating crRNA (tracrRNA), an alternative RNA hybridizes with each crRNA, forming a complex with the Cas9 nuclease. Only when PAMs are located conterminous to the protospacer-decoded portion of the crRNA will Cas9 be directed to stick reciprocal target-DNA sequences to make breaks in the DNA [12]. A detailed classification of these CRISPR-Cas systems and Cas proteins would provide valuable information for modifying and adapting them for various applications.

#### 4. Cas proteins of the CRISPR System

Cas proteins are an essential component of CRISPR system and their varied abilities to edit DNA or RNA make them a potential tool in genome editing. Cas proteins, including Cas9, Cas12, Cas13, and Cas14, have been exploited for genetic engineering [6] and are discussed further below (Tables 2 and 3)

**Table 2.** Host organisms with their cas protein and target molecules.

Host organism	Target Molecule	Protein Name	References

4.1. Cas 1 and Cas 2 Proteins

Cas1-Cas2 exonuclease system is ubiquitous in all the CRISPR-Cas systems and it helps in cleaving both the target DNA and CRISPR array, a crucial step in CRISPR-Cas mechanism. Cas1 and Cas2 proteins are found in E. coli K12, forming a hexameric complex. Cas1 is an asymmetric homodimer with a central ferredoxin fold, while Cas2 is a symmetric homodimer with a central ferredoxin fold [13]. The complex produces crystals diffracting X-rays with a resolution of 2.3 Å. Both are heterozygous molecules that catalyze spacer integration via transesterification reactions. Recent studies have shown that Cas1-Cas2 proteins can recognize the PAM containing prespacer in the

reannealing DNA in repair complexes, and could flexibly coordinate with other accessory proteins to process prespacers and directionality of integration. Cas1-Cas2 protects the host CRISPR system by cleaving the PAM after initial integration of the prespacer into the host CRISPR array and hence could potentially be used as an alternative to systems lacking Cas4, a well-studied protein that acts as a PAM-processing endonuclease. In spite of these advancements, it is still unclear on the upstream CRISPR substrate biogenesis and future investigations into their precise role in adaptation of CRISPR-Cas system would open avenues for their wide spread application in genome editing (Wang et al., 2023, [14]).

#### 4.2. *Cas9 Protein*

Cas9, formerly known as Csn1 or Csx12, is a protein connected to the *Streptococcus pyogenes* CRISPR mechanisms of adaptive immunity. Cas9 protein is the first Cas protein to be employed in genome editing (SpCas9) and its mechanism of action is extensively researched and applied in various organisms [15]. In natural and synthetic CRISPR/Cas systems, the SpCas9 protein functions as a DNA endonuclease and consists of 1368 amino acids in its big multifunctional domain. Cas9 endonuclease consists of six domains of which two are nuclease domains, RuvC and HNH and one is a PAM-interacting domain. The primary function of Cas9 protein is to cut three base pairs upstream of the PAM sequence in dsDNA creating double stranded breaks. Since the CRISPR/Cas9 system was created by fusing twin tracrRNA: crRNA into a single guide RNA (sgRNA), it could cut specific target dsDNA or ssDNA sequences (Figure 2). The cuts generated by CRISPR-Cas9 system could be repaired either by non-homologous end joining (NHEJ) repair or homology-directed repair (HDR). HDR usually requires a template that could be a sister chromatid or exogenously supplied DNA (gene knock-in) with homology arms to DSBs [16]. CRISPR-Cas9 is a preferred tool over other genome editing tools like ZFN and TALEN systems due to its simple design and higher effectiveness. The ability to create and use several sequence-specific gRNAs simultaneously allows for multiplex genome editing and makes it a prime trait development tool. Researchers have widely adopted this system in various fields, including microorganisms, plants, animals, insects, and human cell lines [17]. Despite numerous advances, CRISPR/ Cas9 systems have numerous failings that raise numerous questions about the pitfalls involved in editing. Few major concerns of Cas9 application are on- and off-target mutations and restriction of edits to regions of high GC content because of a “G” rich PAM sequence requirement (Bernabé-Orts et al., 2019, [18]) of this protein. Indeed, the sophisticated CRISPR/ Cas systems with HDR produce unwanted mutations. Still, these off-target mutations can be eased by using a modified interpretation of Cas9 called Null-Cas9 (dCas9), which lacks the endonuclease activity [19]. Cas9 could be used for epigenome editing rather than creating irreversible genome modifications. However, further studies are necessary to improve the specificity of Cas9 function and to reduce off-target mutations [20].

**Figure 2.** The CRISPR/Cas9 mechanism involves six domains: recognition flap (REC I), arginine-rich bridging helix, PAM interaction, HNH, and RuvC. REC I is responsible for hRNA binding, while HNH and RuvC initiate cleavage. B-programmed gRNA binds to Cas9, transforming it into an active form. Cas9 generates a 3bp DSP using HNH and RuvC.

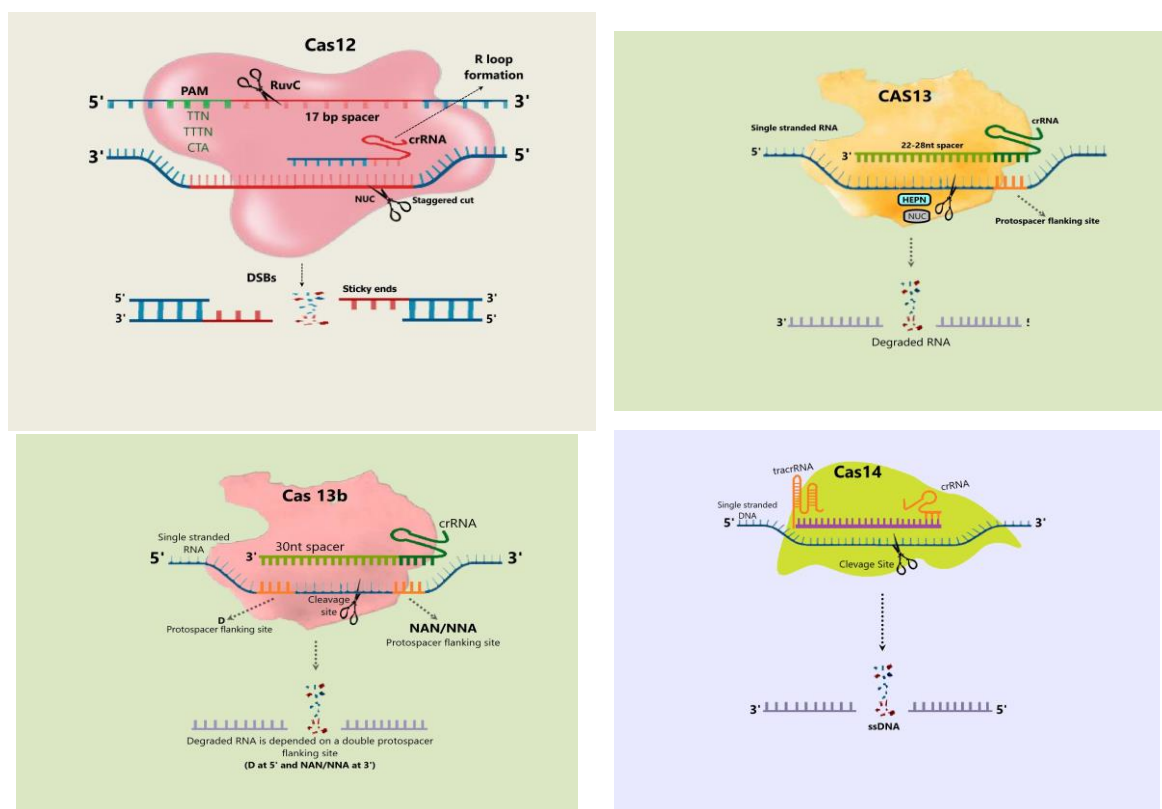

#### 4.3. Cas12 Protein

The CRISPR-Cas system, which was partially repurposed as a programmable genome-editing tool, was identified as an adaptively susceptible mechanism in prokaryotes [21]. In programmable genome editing, the Cas9 and Cas12a proteins are widely utilized. In contrast to Cas9, Cas12a protein has the ability to recognize "T" rich PAM sequences and generate staggered ends that could promote efficient site-directed integration in comparison [18]. As most of the regulatory elements are "AT" rich, Cas12a could serve as an efficient tool for engineering the epigenome modification [22]. Cas12a consists of two main components-protein/effector nuclease and a single crRNA, which is sufficient to process the crRNA unlike Cas9 that requires a tracrRNA to form a mature crRNA [23]. Three homologs of Cas12a viz., FnCas12a (from *Francisella novicida*), LbCas12a (from *Lachnospiraceae* bacterium), and AsCas12a (from *Acidaminococcus* sp.) share similar domain architecture and are widely utilized in plant genome editing technologies [24]). In a recent report, two other homologs of Cas12a viz., Ev1Cas12a and Hs1Cas12a have been shown to produce efficient multiplex genome editing in rice and tomato protoplasts [25]. Cas12a editing has been applied to various crops including rice, wheat, tomato, citrus, soybean and the model plant *Arabidopsis thaliana* [26] with varied editing efficiencies. Recently miniature variants, CRISPR/Cas12j (CasΦ) and Cas12f systems and were discovered with less than half the size of Cas9 and their orthologs were successfully tested in plants [27]. Efforts are underway to generate improved versions of Cas12a with altered PAM specificities [28; 29] and improved temperature sensitivity for its flexible application and efficient delivery into plant systems [30].

#### 4.4. Cas13 Protein

Cas13 proteins are displayed in at least 21 bacterial genomes and it consists of two distinct HEPN (higher eukaryote and prokaryote nucleotide binding) domains and a single protein effector [31] (Figure 3). CRISPR-Cas13 is the only known system among others to target single stranded RNA and owing to this ability, Cas13 has a potent application in plants to target RNA (coding and non-coding) and silence defense responses of RNA viruses [32]. Recent studies have shown that Cas13 independent guide-induced gene silencing (GIGS) could substantially reduce the viral load in tobacco, tomato, and Arabidopsis, even in the absence of Cas13 protein offering a potential system for studying tissue or time specific expression studies which are otherwise difficult to manipulate with other CRISPR-Cas systems [33]. Cas13a orthologs vis., LwaCas13a (Cas13a from *Leptotrichia wadei*) and LshCas13a (Cas13a from *Leptotrichia shahii*) were successfully tested in plants with moderate efficiency. Cas13d subtype, which is a smaller protein than Cas13a has been discovered to perform efficiently at a broad temperature range of 24–41 °C. Modified and programmable Cas13 mutant forms (dCas13, Cas13x) were generated to effectively target specific effectors to specific RNAs in order to elicit specific modifications [34]. RNAs can be selectively targeted to use Cas13 entirely because of the innate crRNA biosynthesis. In contrast to RNA interference, genome changes induced by CRISPR/Cas13 are not restricted to focusing on cytoplasmic transcripts. In expansion, Cas13 selectively knocks off cytoplasmic mRNA transcripts, enabling quicker downregulation of expression [34]. These finding suggests a promising opportunity to deploy this system for generating multigene silencing in polyploid plants [31,35].

**Figure 3.** The CRISPR/Cas12 mechanism involves cleaving the target region near the PAM sequence, creating an R-loop and R cycle. The CRISPR/Cas13a mechanism activates Cas13a protein, which encodes crRNA, NUC particles, and HEPN domains for target RNA. The CRISPR/Cas14 system consists of Cas14 protein, TracrRNA and crRNA, Case 14, and target proteins of ssDNA. The PAM domain meets usability and application criteria for future genetic engineering.

#### 4.5. Cas14 Protein

Cas14, a protein in the CRISPR-Cas framework, has been characterized for its unique biochemical properties. This protein originated in extreme thermophile and shows high affinity to single stranded DNA (ssDNA) without the requirement of PAM sequence for its activity [36]. (Fig-

4). The CRISPR/Cas14 system has been used to detect and genotype single nucleotide polymorphisms (SNPs) and improve resistance to ssDNA viruses in crops [37] Cas14 protein offers several advantages over traditional Cas9 protein. For example, Cas14 is incredibly small, with only 500 amino acids and hence could be delivered to any target organism more efficiently than the Cas9 protein. (Tables 4 and 5). Moreover, Cas14 based biosensors (HARRY) are getting more focus than others like Cas12 and Cas13 proteins because of its improved sensitivity in the detection of diverse targets [38].

The major CRISPR-Cas systems which are currently in use have different pros and cons and there is always a scope to improve their efficiency and build up new approaches to use these systems for varied application across different fields.

Table 4. Comparison of Cas9 vs Cas12 vs Cas13 vs Cas14.

Parameter	Cas9	Cas12	Cas13	Cas14
Size of Protein (Amino Acid)	~1000-1600	~1300	~1400	~400-700
Target	DNA	DNA	RNA	DNA
RNA	Two RNA molecules	Single RNA molecules	Two RNA molecules	Single RNA molecules
Nuclease Site	2 nuclease domains HNH and RuvC	Single nuclease RuvC-Nuc	Target RNA domain HEPN	DNA binding domain RuvC
Pattern of cut	Blunt	Sticky-ended	Degraded	NA
Spacer Size	16-20nt	16-25nt	25-35nt	NA
Protospacer restriction	PAM	PAM	PFS	PAM
Single guide molecular size (Nucleotides, nt)	17-24nt	42-44nt	-64nt	-140nt
Non-specifically cut nucleic acids (DNA or RNA)	DNA(SS)	DNA(SS)	RNA(SS)	DNA(SS)

5. Prime Editing

The double stranded breaks (DSB) caused by CRISPR-Cas9 system usually generates a complex mix of unintended in-del byproducts, translocations and chromosome fragmentations. Although attempts have been made to improve these issues [39,40], they are not accurate enough and with advancements in knowledge of the CRISPR-Cas mechanism, researchers are continuously working on improving and optimizing this gene editing technology. One such technology is named Prime editing, developed by David Liu’s group in 2019. This technology has been shown to have reduced off-targets because of its unique ability to search and replace target sequences without the need of an exogenous donor repair template [41,42]. Prime editing system mainly consists of two components: prime editor (PE-nCas9-MMLV) and PE guide RNA (pegRNA) and its mechanism of action is well studied and improved versions of prime editors have been developed for better accuracy [review by 43]. Because of this unique feature of Prime editing system, it has been successfully used to develop resistance against biotic stress by integrating a 30-nucleotide cis-regulatory element through knock-in with high efficiency in rice [44]. Various methods used to improve prime editing technology have been summarized by [45 & 43]. Improved versions of PE system have been successfully used to generate crop germplasm resources, herbicide tolerance germplasm in rice and wheat by generating specific edits and also designing mutations at existing variant sites [6,43,45]. By using modified prime editor, pCXPE03 in tomato, three genes viz., GAI, ALS2, and PDS1 were edited efficiently and produced lower frequency of off-target byproducts of 0.5%–4.9% [46]. In addition to these, improved plant GRAND pegRNA strategy from mammalian cells was successfully used to generate efficient insertion of protein tags in plants with higher insertion efficiency of 25% [25]. Although all these studies promote its wide spread application in plants, its low editing efficiency is still a concern and improved prime editors are needed to resolve these issues for a better use of this technology (Table 9).

6. Application of CRISPR in Plant Abiotic and Biotic Stress Tolerance

CRISPR-Cas is a robust tool that can be used to knock-out, knock-in or replace a gene element at a target genomic sequence to regulate the expression of a gene at the genome and epigenome level. This inexpensive and efficient tool has been employed to improve the traits of various crops.

6.1. CRISPR in Abiotic Stresses Tolerance

Abiotic stresses like drought, salinity, heavy metal and extreme temperatures greatly affect the plant growth and development and could lead to 50% of crop losses [47]. According to a report, 20% of the aerable land is affected by salinization and the increasing percentage of Earth’s land is expected to get affected in coming years at a faster pace [48]. Plants under salt stress may have negative effects that lower yield and quality. This is due to the induction of osmotic, ionic, and secondary stress. Using CRISPR-Cas9 system, Alam et al. in 2022 [49] developed a rice variety by knocking out OsbHLH024 gene and enhancing the expression of the ion transporter genes OsHKT1-3, OsHAK7, and OsSOS1. 27 [50]. CRISPR/Cas9-induced OsRR22 gene mutation in rice increased its resistance to salt without affecting other agronomic characteristics [51]. It was also employed successfully to alter OsRAV2, and the resultant mutant exhibited increased survivability under salt stress. Furthermore, it has been reported that CRISPR-Cas9 system can significantly increase the resistance of different crops to salt stress by deleting or overexpressing the genes for example tomato SlARF4, rice OsDST

[52], OsNAC041 and OsmiR535 [53], and barley HvITPK1 [54], Arabidopsis AtC/VIF1 [55] and Soybean GmMYB118 transcription factor [56]. Increasing impact of global warming has led to increased drought and temperature stress conditions and by targeting the drought response genes using CRISPR-Cas9 system enhanced drought tolerance has been achieved in various plant species. In rice improved drought tolerance was achieved by targeted mutagenesis of OsERA1 using CRISPR/Cas9 [57]. Other genes of rice viz., OsDST, SRL1 and SRL2, SAPK2 have been edited to improve the plant's ability to have better water retention capacity, lower stomatal density, improved scavenging of reactive oxygen species and have improved drought tolerance [52,58,59]. The *ospyl9* mutant, produced using CRISPR/Cas9, was shown to boost up rice yield and drought tolerance [58]. Additional studies involving CRISPR/Cas editing of ERF family members from rice (OsBIERF1, OsBIERF3 and OsBIERF4), maize (ARGOS8) and wheat (TaERF3) have also shown to improve drought tolerance [60,61]. Ding et al. 2020 suggest that cold stress, encompassing temperatures lower than 20°C and 0°C, obstructs growth and plant development and significantly restricts plant geographical distribution and agricultural output [62]. Low temperatures directly decrease plants' metabolic response, causing osmotic stress, oxidative stress, and other types of stress. CRISPR/Cas9 editing was used to create rice with *pyl1/4/6* triple knockdown. The mutant showed less germination before harvest, a higher yield, and a higher tolerance to temperature than the natural variety. Genes involved in ABA signaling and cell membrane biosynthesis have been targeted in rice using CRISPR-Cas9 system (CBF1, OsANN3, SAPK2, and OsMYB30) and have been found to prevent electrolyte leakage, improve relative electrical conductivity and improved the drought tolerance efficiency by nearly 63% [63 & 60]. Other major abiotic stresses like high temperature and heavy metal stress have also been addressed successfully using CRISPR gene editing in various crops like tomato (BZR1, AGL6 for heat stress tolerance), maize (TGMS5 for heat tolerance) and rice (OsNRAMP1 and OsNRAMP5-Cadmium tolerance, OsARM1-arsenic tolerance, OsHAK1- Caesium tolerance) [60,64]. The list of crops edited using CRISPR-Cas system for improvement of abiotic stress tolerance have been summarized in Table 7.

**Table 7.** Achievement of different targeted gene.

Crop Species	Trait	Gene Targeted	Achievement made	Reference
<i>O. sativa</i>	<ul style="list-style-type: none"> <li>Disease resistance</li> <li>Thermotolerance</li> <li>Grain-length salt tolerance</li> </ul>	<ul style="list-style-type: none"> <li>Mutation and loss of function in OsSWEET14</li> <li>Mutation in EBEs of OsSWEET14 gene</li> <li>Mutations in EBE of three promoters of SWEET11, SWEET13 and SWEET14</li> <li>Knockdown of the Os8N3 in rice</li> </ul>	<ul style="list-style-type: none"> <li>Mutant rice confers strong resistance to African Xoo and Asian Xoo strains</li> <li>Enhanced resistance to locally isolated virulent Xoo strains</li> <li>Stable transgenic rice lines [79] indicated robust, broad-spectrum resistance to Xoo.</li> <li>Transmission of mutations to generations, and enhanced resistance to Xoo in homozygous mutants.</li> </ul>	
<i>M. balbisiana</i>	Enhanced resistance	Mutation in downy mildew resistance 6 (DMR6)	Musa <i>dmr6</i> transgenic mutants of banana showed enhanced resistance to BXW, and did not show any detrimental effect on plant growth	[80]
<i>M. domestica</i>	Disease resistance	Mutation in apple DIPM-1, DIPM-2 and DIPM-4	Resistance to fire blast disease in non-transgenic but mutant apple lines	[81]
<i>S. lycopersicum</i>	Disease resistance	Loss of function mutation in SIDMR6-1 gene	Mutants do not have detrimental effects on growth	[82]

			and had multiple disease resistance <i>P. syringae</i> , <i>P. capsici</i> and <i>Xanthomonas</i> spp.
<i>C. sinensis</i> Osbeck	Canker resistance	Mutation and loss of function in CsWRKY22	Mutant orange plants showed decreased susceptibility to citrus canker [83]
<i>C. sinensis</i> Osbeck	Canker resistance	CRISPR/Cas9-targeted mutation in CsLOB1 promoter in citrus	Promoter editing of CsLOB1 alone was sufficient to enhance citrus canker resistance in citrus. [84]

6.2. CRISPR in Biotic Stress Tolerance

Crop yield up to 20-40% worldwide are accounted to various biotic factors like viruses, fungi and bacteria [65]. CRISPR-Cas system has proven as a robust tool that could specifically knockout undesirable genes and confer plant tolerance to various diseases. Powdery mildew is one of the most destructive types of fungal diseases that crops can suffer, as it significantly reduces crop yield. Higher resilience to powdery mildew in wheat was achieved by knocking out three MILDEW-RESISTANCE LOCUS (MLO) genes which are known to be responsible for the infection, using CRISPR/Cas9. Similarly, in grapes [66] and tomatoes [67] resistance to powdery mildew was achieved through CRISPR/Cas9-mediated reduction of SIMLO and VvMLO. Furthermore, tomato powdery mildew resistance was markedly enhanced by the CRISPR/Cas9-mediated SIPMR4 mutation, although immunity was not entirely restored [68]. Several other devastating fungal diseases like Fusarium wilt and blast cause severe crop losses and lack of any resistant germplasm restrict the possibility of traditional breeding for developing resistant varieties [69]. CRISPR-Cas system was successfully used to edit genes and confer resistance to these pathogens. In rice, OsERF922 and OsSEC3A genes were mutated using CRISPR/Cas9 and the plants tested were shown to be significantly resistant to blast disease at both the seedling and tillering stages [70,71]. A method enabled by CRISPR/Cas9 technology allows for the mutation of the acetylgenase-encoding genes ACER1a and ACET1b to generate distinct resistant materials with increased resistance to bacterial and fungal diseases. Tomato susceptibility gene SIDMR6-1 mutations produced by CRISPR/Cas9 offer resistance against a variety of diseases, such as bacteria, oomycetes, and fungus [72]. Broad-spectrum resistance to bacteria and fungi was demonstrated by CRISPR/Cas9-mediated osnramp1 mutants, which showed decreased catalase (CAT) activity but elevated hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) content and superoxide dismutase (SOD) activity [73]. The list of crops and the genes edited in different crops for abiotic stress tolerance are summarized in Tables 7 and 8.

Table 8. CRISPR/Cas genes intended to confer tolerance against biotic stress.

Stress	Pathogen Factor	Crop	The name of the target gene	References
Insect disease	Plant hopper	Rice ( <i>Oryza sativa</i> )	CYTOCHROME P450 71A1 (OsCYP71A1)	[109]
	Stem borer	Rice ( <i>Oryza sativa</i> )	OsCYP71A1	[109]
	Common cutworm	Soybean ( <i>Glycine max</i> )	CALCIUM-DEPENDENT PROTEIN KINASE 38 (GmCDPK38)	[110]
Virus disease	Rice tungro spherical virus	Rice ( <i>Oryza sativa</i> )	eIF4G	[111]
	Cucumber vein yellowing virus	Cucumber ( <i>Cucumis sativus</i> )	EUKARYOTIC TRANSLATION INITIATION FACTOR 4E(eIF4E)	[112]
	Zucchini yellow mosaic virus (Cucumis sativus)	Cucumber ( <i>Cucumis sativus</i> )	eIF4E	[112]

	Papaya ring spot mosaic (Cucumis virus)	Cucumber ( <i>Cucumis sativus</i> )	eIF4E	[112]
	Tomato mosaic virus	Tomato ( <i>Solanum lycopersicum</i> )	DICER-LIKE 2b (SIDCL2b)	[113]
	Potato virus X	Tomato ( <i>Solanum lycopersicum</i> )	SIDCL2a and SIDCL2b	[113]
Fungus disease	Rice Blast	Rice ( <i>Oryza sativa</i> )	OsERF922 SUBUNIT OF THE	[113]
		Rice ( <i>Oryza sativa</i> )	EXOCYST COMPLEX 3A (OsSEC3A)	[70]
		Rice ( <i>Oryza sativa</i> )	Pi21 and Bsr-d1	[71], [50]
	Powdery mildew	Tomato ( <i>Solanum lycopersicum</i> )	MILDEW RESISTANT LOCUS O (SIMLO)	[114]
		Wheat ( <i>Triticum aestivum</i> )	TaMLO-A1, TaMLO-B1 and TaMLO-D1	[115]
		Grapevine ( <i>Vitis vinifera</i> )	VvMOL3	[115]
	Late blight	Tomato ( <i>Solanum lycopersicum</i> )	POWDERY MILDEW RESISTANCE 4 (SIPMR4)	[67]
		Tomato ( <i>Solanum lycopersicum</i> )	miR482b and miR482c	[113]
		Tomato ( <i>Solanum lycopersicum</i> )	PECTATE LYASE (SIPL)	[116]
	Gray mould	Tomato ( <i>Solanum lycopersicum</i> )	PECTATE LYASE (SIPL)	[116]
Bacterial disease	Bacterial blight	Rice ( <i>Oryza sativa</i> )	SUGARS WILL EVENTUALLY BE EXPORTED TRANSPORTER 13 (OsSWEET13)	[117]
	Citrus bacterial canker	Orange ( <i>Citrus sinensis</i> )	LATERAL ORGAN BOUNDARY 1 (CsLOB1)	[118]
	Bacterial leaf spot disease	Tomato ( <i>Solanum lycopersicum</i> )	JASMONATE ZIM-DOMAIN 2 (SIJAZ2)	[119]

Table 9. List of crops modified by Prime editing technology.

Crop Type	Monocotyledon Crops	Dicotyledon Crops
Prime Technologies	Examples	Examples
Genomic Selection	Rice ( <i>Oryza sativa</i> )	Soybean ( <i>Glycine max</i> )
	Wheat ( <i>Triticum aestivum</i> )	Cotton ( <i>Gossypium hirsutum</i> )
	Maize ( <i>Zea mays</i> )	Sunflower ( <i>Helianthus annuus</i> )
CRISPR-Cas9	Barley ( <i>Hordeum vulgare</i> )	Tomato ( <i>Solanum lycopersicum</i> )
	Sugarcane ( <i>Saccharum officinarum</i> )	Potato ( <i>Solanum tuberosum</i> )
	Sorghum ( <i>Sorghum bicolor</i> )	Canola ( <i>Brassica napus</i> )
Marker-Assisted Breeding	Barley ( <i>Hordeum vulgare</i> )	Common bean ( <i>Phaseolus vulgaris</i> )
	Sugarcane ( <i>Saccharum officinarum</i> )	Pea ( <i>Pisum sativum</i> )
High-Throughput Sequencing (NGS)	Maize ( <i>Zea mays</i> )	Soybean ( <i>Glycine max</i> )
	Rice ( <i>Oryza sativa</i> )	Cotton ( <i>Gossypium hirsutum</i> )
Biotechnology	Sugarcane ( <i>Saccharum officinarum</i> )	Cotton ( <i>Gossypium hirsutum</i> )
	Maize ( <i>Zea mays</i> )	Soybean ( <i>Glycine max</i> )
	Rice ( <i>Oryza sativa</i> )	Canola ( <i>Brassica napus</i> )

Organic and Sustainable Farming Practices	Bamboo (Various species)	Common bean ( <i>Phaseolus vulgaris</i> )
	Rice ( <i>Oryza sativa</i> )	Pea ( <i>Pisum sativum</i> )
Seed Enhancement Technologies	Maize ( <i>Zea mays</i> )	Cotton ( <i>Gossypium hirsutum</i> )
	Rice ( <i>Oryza sativa</i> )	Soybean ( <i>Glycine max</i> )

7. Crop Improvement, Possible Risks and Ethical Concerns of CRISPR-Cas Based Genome Editing

The applications of genetic modification technologies based on CRISPR are applicable in many domains, such as agricultural enhancement and plant functional genomics [8]. Because of its ease of application, CRISPCas9 technology is easily accessible and relatively inexpensive to use. Public sector institutions, including the Consultative Group for International Agricultural Research (CGIAR) are using this technology to help the smallholder farmers to improve crops of less importance to the profit-driven private sectors and the current genome editing projects conducted by CGIAR to improve several crop traits are detailed by Pixley et al., 2022[74]. Genome editing is being applied to more than 40 crops to improve food and feed quality or stress tolerance in more than 25 countries but only six genome edited crops for different traits have been approved for commercialization to date [75]. Although the CRISPR-Cas system has a great potential for use, many countries are unsure about the regulations to be used for growing these genome edited crops [76]. Other major risk factors include generation of off-target mutations [77] and possible break down of natural reproductive barriers that prevent some mutations from occurring in nature [45]. However, much efforts are made to improve computational and bioinformatic tools to minimize off-target edits and to better understand the nature and frequency of these non-target mutations generated using CRISPR technology. Moreover, it is also important to consider that natural mutations occur during every generational advance during traditional plant breeding and the frequency of mutations generated through chemical or radiation are 1000 times higher than the natural mutation frequency and the non-target mutations frequency generated by current genome editing tools [45,78,79]. Hence it is important to assess the risk of using the CRISPR based technology over other traditional methods of plant breeding.

The remarkable potential that CRISPR-Cas9 technology unlocks also raises important ethical and regulatory issues. The act of modifying the genetic code of live beings gives rise to important inquiries on the limits of genetic engineering and the possible consequences of modifying inherent biological functions. The moral implications of using CRISPR-Cas9 for germline editing, in which genetic modifications that are inherited by offspring can be passed down to them, have long been a topic of discussion. The complexities of germline modifications require careful thought in order to avoid unexpected outcomes and guarantee the highest level of responsibility in its implementation. Moreover, the regulatory environment surrounding CRISPR-Cas9 technology is constantly changing, with various nations and authorities taking distinct stances on its supervision. It becomes essential to establish clear rules and regulations governing the use of CRISPR-Cas9 in order to ensure its ethical use, responsible execution, and steadfast dedication to environmental and human safety.

8. Conclusion and Future Perspectives

Nowadays, CRISPR/Cas9 technology is being used to improve the different traits such as abiotic stress tolerance, disease resistance, quality and yield of both the monocots and dicots. Crop genomic

sequences can be modified to give higher yields by diversifying the approaches used to characterize the activities of individual genes. The Cas proteins has boosted the basic, therapeutics and diagnostic research. Because these CRISPR/Cas systems are inexpensive and simple to use, many researchers are using them to investigate the functions of different organisms' genes. Furthermore, identifying the unexplained evolution of Cas masteries, which persist in a variety of microscopic organisms or archaea, would transform a variety of fields, such as the diagnosis of new illnesses, medicines, agriculture, breeding, and so forth. If these proteins' advanced genome-editing potential is fully explored, it may ignite an untapped CRISPR "fever" that might lead to the widespread adoption of compelling and revolutionary CRISPR technologies in the near future.

**Author contributions:** NT, SP, DSM, RKS conceived the manuscript. SM, SN and SP wrote the manuscript with the inputs from NT, DSM and RKS.

**Conflict of interest:** There is no conflict of Interest

**Acknowledgements:** The author thanks to Centurion University of Technology and Management, Bhubaneswar, Odisha, India for providing the necessary support for the completion of this manuscript.
