**Abstract:** This article systematically disproves the notion that entropy is a measure of disorder and disproves Schrödinger's notion of negative entropy (negentropy) using multiple novel and compelling arguments. To mathematically describe the second law of thermodynamics, the concept of entropy was created and defined in the 1860s as heat energy divided by thermodynamic temperature, and the entropy of an object increases when it absorbs heat. This is the uncontroversial and fundamental nature of entropy, which is pivotal to current thermodynamics and from which multiple facts are deduced. These facts consistently disprove the above two widely accepted notions. Multiple biological facts (e.g., life orderliness is encoded and provided by inherited genes rather than entropy decline) can also disprove Schrödinger's negentropy notion. This article further elucidates the reasoning errors of the two notions. Moreover, the second law of thermodynamics and the notion that many natural or social systems tend to become more disordered over time result from distinct statistical probabilities and are hence independent of each other.

**Keywords:** disorder; energy; entropy; life; negative entropy; probability; thermodynamics

---

## 1. The Fundamental Nature of Entropy: The Judgment Criterion

In the 1860s, Rudolf Clausius created the entropy concept ( $S$ ) to mathematically describe the second law of thermodynamics (Box 1) and explain the efficiency of heat-to-work conversion in Carnot cycles[1]. The law states that heat can spontaneously flow from a hot object to a cold object and cannot spontaneously flow reversely. The law involves two parameters, heat energy ( $Q$ ), the kinetic energy of the unordered vibration of molecules in an object [2–4] and thermodynamic temperature ( $T$ ).  $T$  is higher than zero for all objects worldwide, according to the third law of thermodynamics [2–4].

**Box 1. Changes of the entropy of an isolated system**

In an isolated system containing only hot A and cold B, heat spontaneously flows from A to B, and for any time point before A and B reach the same temperature, A is hotter than B ( $T_A > T_B > 0$ ), the heat released by A is equal to the heat absorbed by B ( $Q_B = -Q_A > 0$ ).

The change of entropy ( $\Delta S = \Delta Q/T$ ) of B, A, and the isolated system:

- $\Delta S_B = \Delta Q_B/T_B > 0$  because B absorbs heat ( $\Delta Q_B > 0$ )
- $\Delta S_A = \Delta Q_A/T_A < 0$  because A dissipates heat ( $Q_A = -Q_B < 0$ )
- $\Delta S_{i\text{-system}} > 0$  because  $\Delta S_{i\text{-system}} = \Delta S_A + \Delta S_B = \Delta Q_A/T_A + \Delta Q_B/T_B$   
 $= -\Delta Q_B/T_A + \Delta Q_B/T_B = \Delta Q_B (1/T_B - 1/T_A)$ ,  $\Delta Q_B > 0$ , and  $T_A > T_B$ .

The above inequality  $\Delta S_{i\text{-system}} > 0$  accurately describes in mathematics the second law of thermodynamics [1,2,5].

Clausius invented the Clausius formula,  $\Delta S = \Delta Q/T$ , which means that, at a time point, the increase in the entropy of an object ( $\Delta S$ ) is equal to the heat absorbed by the object ( $\Delta Q$ ) divided by the thermodynamic temperature of the object ( $T$ ) [1–6]. This formula suggests that the entropy of an object increases when it absorbs heat from its surroundings ( $\Delta Q > 0$ ) and declines when it dissipates heat into its surroundings ( $\Delta Q < 0$ ), and suggests that the entropy of an isolated system always increases until its components reach the same temperature (Box 1), which accurately describes in mathematics the second law of thermodynamics [1–5].

The Clausius formula defines the fundamental nature of entropy: entropy is a physical concept analogous to energy because entropy is heat energy divided by thermodynamic temperature [2–4]. This aligns with Rudolf Clausius's statement: "...I have designedly coined the word 'entropy' to be similar to 'energy', for these two quantities are so analogous in their physical significance..." [6] The fundamental nature of entropy, which is uncontroversial and pivotal in current thermodynamics [2–6], is employed in this article as the criterion to judge the correctness of other notions associated with entropy.

The increase in the entropy of an object as a result of heat absorption can lead to at least four types of changes: for example, a stone, metal, or ideal gas becomes hotter; an ice changes from a solid to a liquid state; a solar battery gains electrical energy; and carbon dioxide, along with water, can form glucose through heat-absorbing organic synthesis (photosynthesis) in plant leaves [7,8]. In the first two types of changes, the increased heat or entropy of the object remains as heat energy, which can be dissipated if the surroundings become colder. In contrast, some of the increased heat or entropy of the object in the last two types of changes is stored as electrical energy or chemical energy, which can be stored in the objects even if the surroundings become colder<sup>7</sup>.

## 2. Boltzmann's Statement Regarding Entropy and Life

Ludwig Boltzmann stated in 1886 that animals struggle for the entropy that is transformed from the solar energy in plants [9] (Box 2).

**Box 2. A part of the lecture of Boltzmann on entropy and life<sup>9</sup>**

... The general struggle for existence of animate beings is therefore not a struggle for raw materials. —these, for organisms, are air, water and soil, all abundantly available —nor for energy, which exists in plenty in any body in the form of heat (albeit unfortunately not transformable), but a struggle for entropy, which becomes available through the transition of energy from the hot sun to the cold earth. In order to exploit this transition as much as possible, plants spread their immense surface of leaves and force the sun's energy, before it falls to the earth's temperature, to perform in ways yet unexplored certain chemical syntheses of which no one in our laboratories has so far the least idea. The products of this chemical kitchen constitute the object of struggle of the animal world...

This statement is correct according to the fundamental nature of entropy because the entropy of plants increases when they absorb heat from sunlight, and the increased entropy or energy is stored as chemical energy in carbohydrate molecules through photosynthesis (Section 1)[7,8]. Animals can use the entropy or energy stored in the carbohydrate molecules for their movement, maintenance of their body temperatures, and other purposes, when the entropy or energy is released through the metabolic degradation of the carbohydrate molecules in plants, which serve as animals' food. Animals do not struggle for the heat energy abundant on Earth that they cannot utilize.

**3. The Boltzmann Formula of Entropy**

In 1900, Max Planck defined entropy with the equation,  $S = k \ln W$ , which he termed the Boltzmann formula because the equation originated from Boltzmann's views that the second law of thermodynamics can be explained with the statistical probability associated with heat transfer[9,10]. In the formula,  $k$  represents the Boltzmann constant ( $1.38065 \times 10^{-23}$  J/K), and  $W$  is from the German "Wahrscheinlichkeit", which means probability[11], representing an elusive quantity about a probability associated with heat transfer[9,10].

To combine the Clausius formula and the Boltzmann formula, it can be deduced that, at a time point:

$$\Delta S = \Delta Q/T = S_2 - S_1 = k \ln W_2 - k \ln W_1 = k (\ln W_2 - \ln W_1) = k (\Delta \ln W)$$

$$\Delta \ln W = \Delta Q/(kT)$$

This shows that  $W$  is a quantity associated with heat energy and thermodynamic temperature. Later,  $W$  was translated in English with the words of complexions, permutations, thermodynamic probability, or multiplicity (the count of microstates)<sup>11</sup>. Here, we just need to know that these terms and the Boltzmann formula do not challenge the fundamental nature of entropy defined by the Clausius formula[9–11].

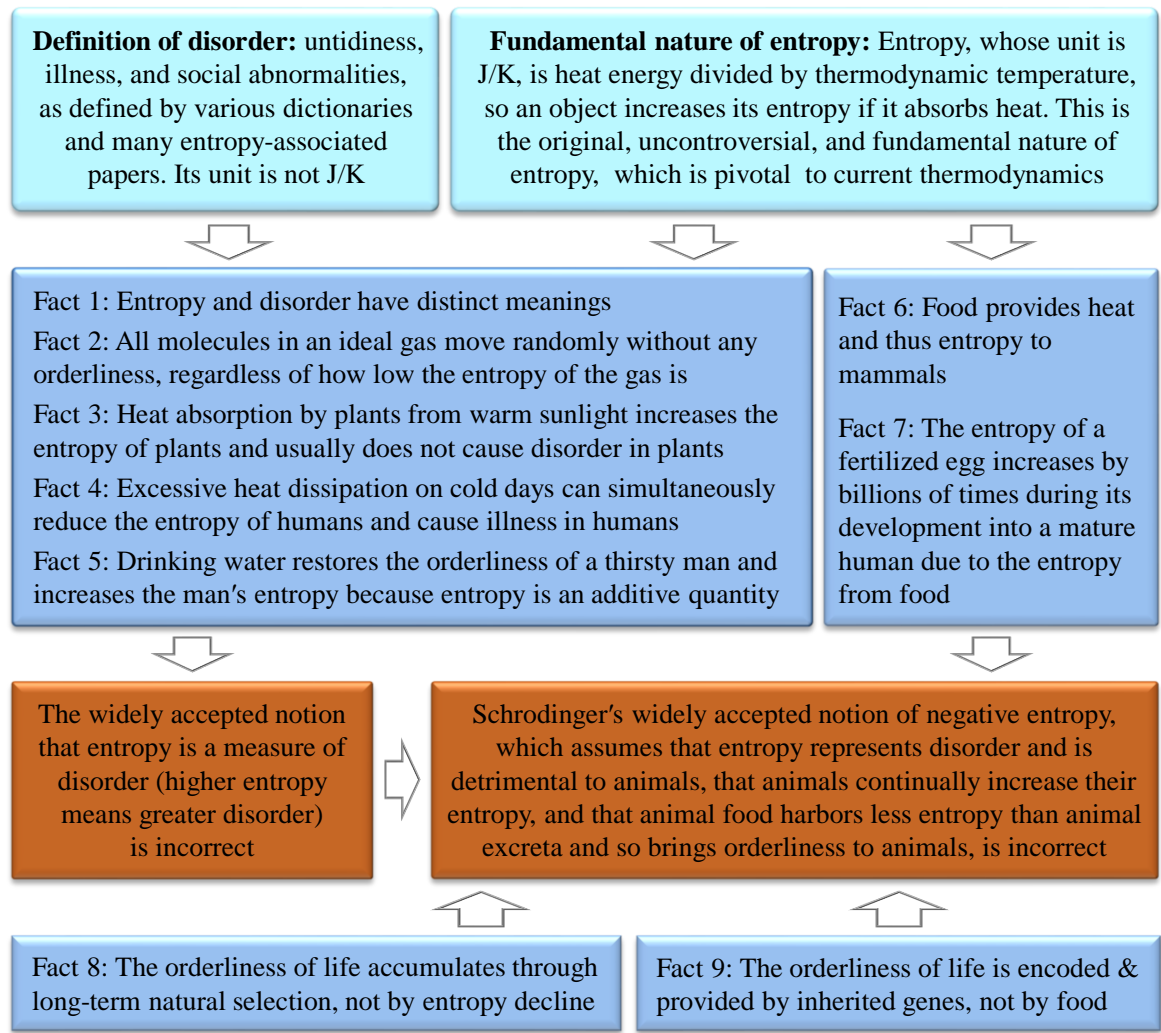

**4. Modern Explanations of the Second Law of Thermodynamics**

The Clausius formula and the Boltzmann formula were established before or in 1900, when the essence of heat transfer remained unknown. According to modern knowledge regarding the structures of atoms and molecules and electromagnetic waves, heat can be transferred through conduction (molecule collisions) in solids, convection (molecule mixing) in gases or liquids, and

radiation through electromagnetic waves[2,4]. In all these three types of heat transfer, heat or energy flows less from a cold object to a hot object than from the hot object to the cold object[2,4], which explicitly explains the second law of thermodynamics.

5. Entropy Cannot Represent Disorder

In the 1880s, Hermann von Helmholtz used the word “disorder” to describe entropy, possibly from which the notion that entropy represents disorder (higher entropy means greater disorder) emerged[12]. This notion has been widely stated in various dictionaries[13], encyclopedias[5,6,14,15], textbooks[2,4], and many research articles[16–23], although this notion has faced a few challenges[3,24–27]. This notion can be disproved for the following reasons (Figure 1).

**Figure 1.** Multiple facts consistently prove that two widely notions associated with entropy are misconceptions.

(1) Entropy and disorder have distinct meanings. According to the fundamental nature of entropy, entropy is analogous to energy with the unit of J/K[2–4]. By contrast, according to the explanations of disorder in various Oxford dictionaries[28], the Collins English Dictionary[29], and some entropy-associated research articles[16–19], disorder means untidiness, illness, and social abnormalities (e.g., violence or rioting). Disorder usually stems from the decline in the orderliness of a system, and its unit cannot be J/K. Although some people argue that the “disorder” in thermodynamics means different things from the “disorder” in biology, social sciences, or usual thinking[14], the notion that entropy represents disorder has been widely applied to investigate the “disorder” in biology and social sciences[16–23], as exemplified by Schrödinger's negative entropy

notion, which will be detailed below. Moreover, what we argue is just that entropy does not mean the “disorder” in biology, social sciences, or usual thinking.

(2) No molecules in an ideal gas move in an orderly manner, regardless of how much the entropy of the gas is reduced. This suggests that entropy cannot represent disorder even in the classical system of ideal gas in thermodynamics.

(3) Heat absorption by plants from warm sunlight, which increases the entropy of plants, usually does not cause or add disorder to plants. Therefore, entropy cannot represent disorder in plants.

(4) Excessive heat dissipation of humans on cold days can reduce the entropy and cause disorder in human bodies, i.e., insufficient entropy can increase disorder in humans. Therefore, entropy cannot represent disorder in humans.

(5) Drinking water can restore the orderliness of a thirsty man, which simultaneously increases the entropy of the man because entropy is an additive quantity in physics (e.g., the entropy of the isolated system composed of object A and object B in Box 1 is equal to the entropy of object A plus the entropy of object B) [2–4]. This fact contradicts the notion that entropy represents disorder in humans.

## 6. Errors in Schrödinger's Negative Entropy Notion

Nobel laureate Erwin Schrödinger stated in 1943 that life relies on negative entropy (negentropy)[30,31], which encompasses four viewpoints shown in Box 3.

Although Schrödinger's negentropy notion contradicts Boltzmann's correct statement (Section 2), is based on the incorrect notion that entropy represents disorder (Section 5), and erroneously substitutes the microstates ( $W$ ) in the Boltzmann formula with disorder ( $D$ ) in its reasoning (Box 3), it has garnered widespread acceptance for nearly 80 years, with only a few criticisms[32–35]. Notably, Google Scholar showed at the end of 2023 that Schrödinger's book, *What is life*, had been positively cited approximately 10,000 times mainly due to the inclusion of this notion. In 2022 and 2023, this book was cited for more than 1,000 times by authors from various countries[32–42], with few doubts about this notion. Coinciding with the popularity of this notion, English Wikipedia and other academic websites deliberately added the word “negative” with brackets in Boltzmann's statement in Box 2 before “entropy”[43,44]. However, it is unlikely that Boltzmann neglected the word “negative” because the concept of negative entropy was coined several years after his death and Boltzmann's statement is correct according to the fundamental nature of entropy (Section 2).

The first viewpoint of Schrödinger's negentropy notion that a living organism continually increases its entropy is incorrect because, according to the fundamental nature of entropy, healthy humans are consistently releasing heat to their surroundings as their bodies are usually hotter than their surroundings, and thus they consistently reduce their entropy except when they are eating, drinking, or absorbing heat from sunlight or other warm surroundings.

The second viewpoint of Schrödinger's negentropy notion that entropy represents disorder and is thus detrimental to animals has been disproved in Section 5. Furthermore, in biology, animal lives are supported by three pillars: orderliness, constituent materials, energy or entropy (Figure 2), like the software (orderliness), hardware (constituent materials), and energy required to operate a computer. The orderliness is encoded and provided by genes inherited from parents[45], while the constituent materials and the energy are mainly from food.

**Box 3.** Two parts of the book *What is life*. The underlined sentences constituted the four viewpoints of Schrödinger's notion.

[Part 1] ... a living organism continually increases its entropy, or, as you may say, produces positive entropy and thus tends to approach the dangerous state of maximum entropy, which is of death. It can only keep aloof from it, i.e. alive, by continually drawing from its surroundings negative entropy—which is something very positive as we shall immediately see. What an organism feeds upon is negative entropy. Or, to put it less paradoxically, the essential thing in metabolism is that the organism succeeds in freeing itself from all the entropy it cannot help producing while alive...

[Part 2] ... If  $D$  is a measure of disorder, its reciprocal,  $1/D$ , can be regarded as a direct measure of order. Since the logarithm of  $1/D$  is just minus the logarithm of  $D$ , we can write Boltzmann's equation thus:

$$-(\text{entropy}) = k \log (1/D)$$

Hence the awkward expression 'negative entropy' can be replaced by a better one: entropy, taken with the negative sign, is itself a measure of order. Thus the device by which an organism maintains itself stationary at a fairly high level of orderliness (= fairly low level of entropy) really consists in continually sucking orderliness from its surroundings. This conclusion is less paradoxical than it appears at first sight. Rather could it be blamed for triviality. Indeed in the case of higher animals we know the kind of orderliness they feed upon well enough, viz. the extremely well-ordered state of matter in more or less complicated organic compounds, which serve them as foodstuffs. After utilizing it they return it in a very much degraded form—not entirely degraded, however, for plants can still make use of it (These, of course, have their most powerful supply of negative entropy in the sunlight)...

**Figure 2.** Three pillars of animal lives and their origins.

The third viewpoint of Schrödinger's negentropy notion that animal food contains less entropy than animal excreta and hence brings orderliness to animals is incorrect because it contradicts the fact that, in biology, the orderliness of life is encoded and provided by inherited genes and accumulates through long-term natural selection, neither provided by food nor suddenly emerging due to entropy decline (Figure 2)[45]. Furthermore, food provides humans with heat and thus entropy to support humans' lives with energy. Schrödinger's assumption that animal food contains less entropy than animal excreta is incorrect because food metabolism dissipates heat, and hence animal food contains more entropy than animal excreta. The entropy of a fertilized egg increases by billions of times during its development into a mature human as entropy is an additive quality, due to the entropy from the food of its mother or itself.

The fourth viewpoint of Schrödinger's negentropy notion that sunlight provides much negative entropy to plants is incorrect because, according to the fundamental nature of entropy, the entropy of plants, stones, ices, and other objects increases when they absorb heat from sunlight. Some of the energy or entropy absorbed by plants is stored as chemical energy in carbohydrate molecules through heat-absorbing photosynthesis[8]. Furthermore, in biology, sunlight or any type of energy cannot directly provide orderliness to plants, and the orderliness in plants is also encoded and provided by inherited genes and accumulates through long-term natural selection[45].

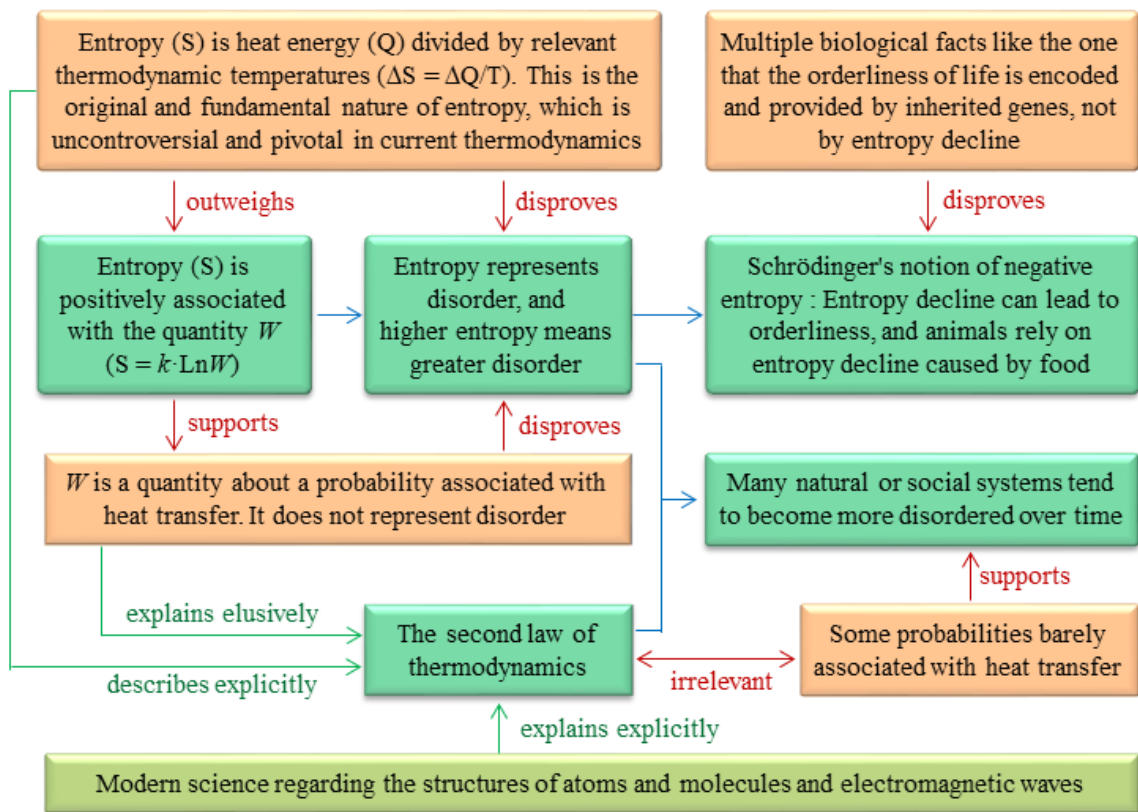

In recent decades, negentropy has also been employed to represent information[46], which is also controversial[30,47].

## 7. Misuse of the Second Law of Thermodynamics

The second law of thermodynamics, which states that heat can flow spontaneously from hot objects to cold objects and cannot flow reversely, has been frequently misused. For example, it was assumed by researchers from various fields that many natural or social systems tend to become more disordered over time due to the second law of thermodynamics[2,4–6,18,19,32,35–42]. The assumption that many natural or social systems tend to become more disordered over time is inherently correct due to some statistical probabilities because it is more probable for these systems to stay at a disordered status than at an ordered status. However, these statistical probabilities are barely due to heat transfer. Therefore, the assumption that many natural or social systems tend to become more disordered over time and the second law of thermodynamics result from distinct statistical probabilities, making them independent of each other.

The reasoning errors behind the two notions and some misuses of the second law of thermodynamics are given in Figure 3.

**Figure 3.** Reasoning of some notions about entropy. The erroneous reasoning of the two notions disproved in this article, the major reasoning of this article, and the three approaches in explaining or describing the second law of thermodynamics are shown with blue, red, and green arrows, respectively.

Interestingly, although many natural or social systems tend to become more disordered over time due to statistical probabilities, we have explicitly explained in recent years that some principles of physics and chemistry (e.g., the second law of thermodynamics), features of the Earth, and features of carbon atoms and other carbon-based entities (e.g., organic molecules and organisms) lead to three mechanisms that have driven inanimate materials to evolve into complex organisms and societies on Earth, and the evolution demonstrates a natural tendency to increase orderliness[48].

8. Conclusions

Although the two notions disproved by this article have faced a few challenges in the past decades, the challenges, which were largely from the perspective of physics[3,25–27,32–34,49], have not gained sufficient attention. This article clarifies the original, uncontroversial, and fundamental nature of entropy, from which multiple facts regarding physics (e.g., ideal gases, solar battery), chemistry (e.g., organic synthesis reactions), and biology (e.g., the roles of genes and the heat requirement of humans) are deduced. These facts constitute novel and compelling arguments to systematically disprove the two notions. This article clarifies the reasoning errors of the two notions regarding entropy. Moreover, this article shows that the second law of thermodynamics and the notion that many natural or social systems tend to become more disordered over time result from distinct statistical probabilities, and they are hence independent of each other.

These two incorrect notions could have deeply influenced various fields in the natural and social sciences in a misleading manner for several decades[3,24–27,32–34,49,50]. They add much difficulty

to the understanding of entropy and thermodynamics. It is imperative to revise relevant textbooks and dictionaries in order to minimize their negative impacts.
